THE Minister of Health on March 11th received a deputation from the Welsh Parliamentary Party, who asked him to make an appointment to the chairmanship of the Welsh Board of Health, an office unfilled since the resignation of Sir Thomas Hughes. The Minister said he did not think it necessary to discuss the history of this question, but he recognized the force of the claim, and accepted the principle that a chairman should be appointed.

INDIAN MEDICAL DEGREES.

The General Medical Council and Indian Qualifications.

HISTORY OF A TEN-YEAR CONTROVERSY.

THE General Medical Council, through its Executive Committee, has taken the important decision of refusing to recognize for the time being the medical degrees of the Indian Universities (Bombay, Calcutta, Lucknow, Madras, and Punjab) as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery in this country. For some years past the recognition given to these degrees has been conditional and renewed for short periods; the recognition now lapses entirely.

This decision will not be unexpected by those who have studied the weighty addresses which Sir Donald MacAlister delivers every session from the chair of the Council. During the last ten years those addresses have contained a recurring reference to the Indian universities and the continuance of the recognition of their degrees as entitling the holders to have their names inserted in the British *Medical Register*. When the present controversy began it did not seem likely to be protracted or enlarged. The General Medical Council, for its part, was desirous of helping the medical colleges in India to overcome some admitted deficiencies which were revealed in the years following the war, and the universities, for their part, gave evidence of a desire, in face of obvious difficulties, to bring up their standards to those required by the Council.

The Council has not only shown great patience in handling the situation, but twice during these ten years the chairman of its Examination Committee (Sir Norman Walker) has visited India at the invitation of the Government, and the Council also approved the appointment of an able and experienced officer of the Indian Medical Service as an inspector, upon whose reports the recognition of the university degrees has from time to time been conditionally continued. Neither Sir Norman Walker nor Colonel Needham, in their visits to the colleges, acted as a mere inspector; they conceived it as their function to consult with and advise the Indian educational authorities, always with a view to some more satisfactory arrangement than a conditional recognition from year to year. Of late, however, certain events in India have intensified the difficulties, and a spirit, not of apathy, but of resistance, has manifested itself, which, reflected in some words used in the Legislative Assembly last autumn, has had the effect of delaying a satisfactory settlement, if not of destroying its prospects altogether.

The Position of the General Medical Council in Respect to India.

It will be useful to place clearly on record the precise interest of the General Medical Council in Indian degrees and diplomas. The General Medical Council has no jurisdiction in India, no right of intervention in Indian medical education so far as India itself is concerned. If no medical graduate of an Indian university proposed to practise in Great Britain or in any country with which Great Britain has reciprocity, or to apply for a commission in His Majesty's service, the Council would have nothing to say. If it were simply a question of suitable professional training for doctors practising in India under Indian conditions, the authorities there, with their special knowledge of local requirements, would be the best and indeed the only judges. India is autonomous, and the Council has no power to intervene. But when East meets West (as it does continually), and the Council is called upon to recognize an Indian qualification as equivalent to a British one for registration in Great Britain, its statutory duty under the Medical Act of 1886 is to inquire into the conditions under which the qualification has been obtained and the measure in which these conditions fulfil the requirements, not of India, but of Great Britain. The President of the Council has made the point as clear as language can make it. "Our primary interest," he said, at the November session, 1928, "is that recognized Indian medical degrees shall guarantee a standard of proficiency sufficient for practice in this country. It is this interest, which we cannot forgo, that alone justifies our intervention in Indian medical education." The Council is the body whose recognition of Indian medical diplomas for registration is by law equivalent to a guarantee of their sufficiency for effective practice of medicine, surgery, and midwifery beyond the limits of India.

As with most other debates, the roots of this controversy extend far beyond the immediate point at issue. Many factors enter into the situation, the most assertive at the moment being Indian nationalism, proud, sensitive, instinctively suspicious of British ideals of education and character. Indian customs, like that of purdah, which has limited the opportunities of obstetric instruction (where the trouble began), have to be taken into account. Then there is the necessity, which the Indian is under, of pursuing his studies in a foreign tongue, so that while his acquaintance with English textbooks may be word-perfect, he suffers often throughout his curriculum from inability to follow entirely the conversational English of the clinic and the examination room. The further fact has to be reckoned with—the fact out of which, the present Prime Minister once said, the difficulties of government in India arise—that India is a continent of peoples whose civilization is advancing at different rates of progress. Even the climate, which makes it harder in India than in England to work throughout the three academic terms a year, is not to be disregarded.

The Rise of Indian Medical Education.

Until recent years medical education in India was directed by the Indian Medical Service. The surgeons of the East India Company, the body under which, up to the middle of the last century, Indian affairs were conducted, gave the first impulse to the medical education of the Indian student. At first it was little more than an apprenticeship in dispensing, but even a hundred years ago the medical student, as the term is understood in the West, began to emerge. Regular college instruction was provided, at first in chemistry, anatomy, and materia medica, and later, as the benefits of the plan became apparent, in all the subjects of the medical curriculum. The colleges which were established at Calcutta, Madras, and Bombay, and afterwards at Lucknow and Lahore, were all Government institutions, and in the closest relationship with the Indian Medical Service. The professors were presidency officers—not whole-time professors, but engaged in civil practice as well—and for a long period they were all Europeans.

It was in these circumstances, with the I.M.S. acting as sponsor for medical education in India, and spreading Western ideas of medicine, surgery, and sanitation, that, in 1892, the General Medical Council first recognized an Indian medical degree as entitling the holder to have his name on the British *Register*. No doubt the members of the Council sitting in London at that time knew little about the actual conditions of instruction and training in India, but they did know that the teachers and examiners were all men who had been educated in British schools and were carrying the spirit and tradition of those schools into their Eastern environment. The fact that entrance to the I.M.S. could only be gained by passing an examination in London led to almost all the candidates for that service, both Indian and European, being holders of British qualifications.

The Indian Medical Service, following upon the recent Indian reforms, has undergone a drastic transformation. From certain points of view it is only the simulacrum of its former self. Another important change has been the devolution of medical administration, including the provision for medical education, from the central to the provincial Governments. The latter, under the Government of India

Act, 1919, have a large measure of independence. These changes have been followed, as was only to be expected, by a great diminution in the proportion of European teachers in the older colleges, while in two additional colleges established in recent years and affiliated to the Universities of Calcutta and Bombay respectively, the professorial staff includes no Europeans.

The curriculum in India differs at some points from the one followed in this country. The custom which obtains here of providing for registration of medical students subject to their passing a recognized preliminary examination in arts, and in addition a practical and theoretical examination in chemistry and physics, does not hold good in some of the Indian universities. In such universities the custom is, after matriculation, which is sometimes passed at the age of 14, to require students before admission to a medical college to pass a university intermediate arts and science examination, or its equivalent, after two further years' study. As the matriculation standard in India is not accepted as the equivalent of the recognized preliminary examination required from intending medical students in this country, the single intermediate examination, which includes chemistry and physics, operates in lieu of the two separate examinations required from British students. The number of students passing the intermediate is greater than the number of vacancies in the medical colleges, and thus a further selection is necessary, a selection said not always to be based on educational grounds.

No student of the history of medicine in India would withhold praise for the excellent work which the Indian medical colleges have accomplished in the past. The best tribute to this work is the high honours which some Indian students have obtained in British examinations. During the war conditions changed for the worse, as they did in many other fields, owing to overcrowding and pressure. The immediate matter which opened up the present controversy was the revelation of a discrepancy between regulation and practice in midwifery instruction. Information on this point reached the General Medical Council in 1920. The subject was one in which it was always difficult in a country like India to arrange for practical instruction. The inadequacy of obstetrical training was at that time recognized, and recently commissioned officers of the I.M.S. who had graduated at colleges where the training was obviously inadequate were required to go for an intensive course to Madras, where opportunities were more abundant.

The Council, on learning that matters were not as they should be in midwifery, addressed a letter of inquiry to to the universities, and after receiving the replies the Executive Committee—which in these questions acts with plenary powers as if it were the Council itself—resolved that unless it received by a given date information that the arrangements and requirements with regard to midwifery had been brought into satisfactory accordance with the Council's resolutions, the recognition hitherto granted to the degrees must terminate. The universities pleaded—a plea which was endorsed by the Secretary of State (the late Mr. E. S. Montagu)—for an extension of time to reform the midwifery and gynaecological part of their curriculum. A temporary arrangement was arrived at—namely, that the Council should nominate one of its members to the Government of India as a visitor to the Indian universities. The result was that early in 1922 Sir Norman Walker, a man with exceptional experience of educational administration, left for India.

Sir Norman Walker's visit created in India an impression of good will. The Indian universities were satisfied that means must be found for resolving the perplexities regarding the standard of obstetrical knowledge. Some of them expressly accepted his suggestions for the improvement of the teaching of midwifery. He dealt, equally sympathetically, with inadequacies in other respects which had become apparent.

A Special Inspector Nominated.

One very important outcome of Sir Norman Walker's report on his return was the proposal that the Government of India should be invited to appoint an officer as special inspector of the universities. The choice fell upon Colonel R. A. Needham, who had had twenty years' experience in the I.M.S., and was at the time Deputy Director-General. The Secretary of State approved the proposal, and Colonel Needham commenced his duties forthwith and submitted his first reports in 1923. Although called an inspector, he had wider functions—namely, to endeavour to co-ordinate the standards in all essential branches of medical training at the different colleges, and to report to the General Medical Council regularly on the maintenance or improvement of the standard, so that recognition might be continued from year to year. Colonel Needham's reports, which were most carefully framed, were highly valued by the Executive Committee. He made reference to defects as he saw them, such as congestion in the colleges, or inadequacies of teaching, or deficiencies in the examination, but he was also careful to acknowledge every effort at improvement, both for what it was and what it promised. Some of the colleges were evidently concerned, apart from the question of external recognition, to provide better facilities for study in midwifery, to extend the curriculum in general (which varied in different parts of India between thirteen and eighteen academic terms), and to extend the too limited period of hospital study after the examination in anatomy and physiology.

An unfortunate episode was the refusal of Calcutta University in June, 1924, to admit the inspector to be present at its final examination. The university was warned that in the absence of a report the conditional recognition would automatically terminate. No report was forthcoming, and the recognition of the Calcutta degrees lapsed in November, 1924. After that date, for four years, the degrees granted by Calcutta did not confer a title to registration in this country. Calcutta made some approaches to the Council in 1925, but the Executive Committee was unable, on the information afforded, to resume recognition, and so matters continued until 1928, when Calcutta applied for recognition of its degrees, and stated that it had revised its regulations. Inspections were consequently resumed, and in the absence of Colonel Needham on leave, Colonel Megaw, I.M.S., was commissioned to visit and report, with the result that the recognition of the Calcutta degrees was accorded, as with the other universities, conditionally, and for a limited period.

Meanwhile, at the end of 1926, on the proposal of the then Secretary of State (Lord Birkenhead), Sir Norman Walker paid a second visit to India. His object was to see the courses of study and the examinations at the universities, to remove difficulties as far as possible, and to have regard to the new situation, now rapidly developing, whereby fresh universities and colleges, including faculties of medicine, were in process of formation in many parts of the Indian Empire. The years 1922–27 saw a large increase in the number of colleges in India, and scattered as they were from Bombay to Rangoon, and from Lahore to Madras, they rendered the conditions of regular visitation and inspection by the direct agency of the Council almost out of the question.

Sir Norman Walker's report on this second visit (fully summarized in the *British Medical Journal*, ii, 1927, p. 312) is perhaps the most comprehensive of recent documents on the subject of Indian medical education. It contains many valuable suggestions, and the picture it gives is, on the whole, reassuring. Sir Norman Walker found excellent maternity hospitals at Madras and Bombay, and the prospects of such at Calcutta and Lahore. He praised the hospital departments in many particulars, especially in respect to ophthalmology. But he pointed out certain defects, such as the isolation of the examinations, the fact that the examiners were all more or less connected with the college or district in which the examination was held, whereas in this country examiners from other universities are brought in; and another point emphasized was the need for maintaining uniformity in examinations from year to year by the appointment of examiners for a certain term.

An All-India Council Mooted.

The principal matter which grew out of Sir Norman Walker's report, however, was the need for new steps to be taken in India itself for the setting up of a responsible and co-ordinating central authority. The existence of conditional recognition from year to year on the report

of an inspector to a body sitting in London was unsatisfactory alike to those who sought recognition and those who bestowed it. However able the inspectors, and whatever good will was shown to the colleges, it could only be a temporary expedient. The time had come when India itself should give some guarantee of uniformity of standards through an authoritative body with which the Council in London could consult.

The suggestion took the form of an All-India Council, whose relation to the various colleges would be not unlike the relation of the General Medical Council to the examining bodies in this country. It is worth while to turn from India for a moment to consider what that relation is. The universities are independent and autonomous, and may impose what conditions they like as to the granting of their medical degrees. But the General Medical Council —by virtue of its right to require information about the course of study and examination for qualification, to inspect the final examination, and to report defects to the Privy Council, which may suspend the right of registration of qualifications granted by the university in default —acts as a co-ordinating and controlling influence. As a matter of fact, conditions being what they are in this country, this disciplinary possibility is quite in the background, and the Council, which itself is composed largely of representatives of the teaching and examining bodies, exercises a benevolent rôle by the suggestions which it makes from time to time for improvement in the curriculum and by circulating among all the bodies the views and practice of each. There may be no exact analogy in other professions for the position of the General Medical Council in this respect, but it must be remembered that, while it is important to conserve the independence of the universities, the public interest is involved in medicine to a greater extent than in other faculties, and therefore a minimum standard must be exacted from all.

The medical colleges in India from the first were isolated units, organized by and dependent on the Government, and staffed by Government medical officers. When a university was founded in their presidency or province they became colleges of the university, still retaining, however, in great measure their independence. So long as the work of the colleges integrated with that of the Indian Medical Service a certain amount of co-ordination was possible. But with the coming of provincial Governments into control of the administration, including university appointments, the colleges lapsed into a greater insularity than ever. Provincial medical councils have been set up, but these do not concern themselves with the maintenance of standards of medical degrees granted by provincial universities, and from the mere fact of geography they could not serve as a means of maintaining uniformity of standards throughout India. At present there is no co-ordinating body in India, and for the General Medical Council to endeavour to act as such would in the nature of the case be ineffective. The system which has obtained for the last seven or eight years has been temporary, and has now become unworkable.

A Temporary Commissionership of Standards.

An All-India Medical Council therefore seemed to offer the way out, one that did not trench on Indian prestige and at the same time satisfied the General Medical Council as furnishing a body with which it could discuss questions of recognition. It was acknowledged, however, that the setting up of such a body must take time. What was to happen meanwhile? Was there to be a hiatus in the recognition of the degrees or an attempt to continue the increasingly difficult procedure of inspection under the aegis of the Council? To bridge the gap it was proposed to set up a Commissioner of Medical Qualifications and Standards, an official whose appointment would be by the Government of India, who would have his headquarters at Delhi, and who with his staff would continue and expand the work already done by the Council's inspector. The reports of such a commissioner would be accepted by the General Medical Council as were those of its own visitor. The central and provincial Governments agreed to this course, and at the end of 1928 it seemed that this vexed question of Indian qualifications was at last approaching a settlement. A bill for the establishment of an All-India Medical Council had been introduced into the central Legislature. The bill provided that this body should exercise supervision over the standard of professional teaching and examination throughout India, having special regard to the external and central or non-provincial aspects of medical qualifications. The appointment of a central commissioner had been approved by the Government of India, for one year in the first instance, and the Secretary of State had suggested that it was desirable to offer the appointment to Colonel Needham—a nomination with which the General Medical Council was heartily in accord, having had experience of Colonel Needham's special qualifications, and knowing how desirable it was that the commissioner should be familiar with British standards. The pay of the officer was even fixed. On the strength of all this the Council continued provisionally the recognition of the degrees of Bombay, Calcutta, Madras, Lucknow, and Lahore for a further period, postponing the consideration of recognition of those of Patna and Rangoon until it received the reports from the new commissioner.

The Impasse Created by the Legislative Assembly.

Shortly before he was due to sail so as to reach India in time for examinations to be held at the end of 1929, Colonel Needham received an intimation from the India Office cancelling his appointment. The reason for this was the action taken in the Legislative Assembly. The Finance Committee of the Legislature had given some warning of what might follow by rejecting the credit for the appointment of the commissioner. The Government, however, brought the matter before the Assembly, and there the suggested arrangement for the commissionership was opposed by the Nationalist and Congress parties on the ground that the creation of the post was of no urgency, but might very well be postponed until the following session. The objection really amounts to this: that India, while not averse from an All-India Medical Council, regards the proposal for filling the necessary interregnum by the temporary appointment of a commissioner as reflecting on Indian prestige. Many of the arguments used by Nationalist members were captious. One objection was that the officer proposed for the appointment belonged to the Indian Medical Service (although the I.M.S. has mothered Indian medical education); another, made by a Hindu leader, was that the proposal involved disrespect to the Indian universities, which, the speaker said, he would rather close than see submitted to this indignity; and there was much talk of dictators and British tyranny. The position of the central and local Governments, which, aware of the gravity of the case, supported the proposal, was put forward, but after a prolonged discussion the opposition was still dissatisfied, and the motion was "talked out." An effort was made to secure the continuation of the debate on the following day, but this was refused by the President of the Assembly, and the session came to an end without any decision being taken.

In view of what had happened the Government of India asked that Colonel Needham should not sail, and the Secretary of State could do no other than comply. It was stated that at the next session, early in the present year, the matter would again be brought forward, but in the meanwhile not only has the proposal for a Government commissioner broken down, but the formation of an All-India Council is stayed. The responsibility for this grave result cannot be placed on the General Medical Council. In his reply to the Secretary of State on "these perplexed and perplexing matters," the President of the General Medical Council stated that the Executive Committee had postponed its final decision until its meeting in February, but he added that the inevitable absence of authoritative reports on the actual standards of study and examination for Indian medical qualifications was of serious import. The committee would be deprived, by the action taken in India, of the guarantees of sufficiency necessary under the Medical Act of 1886, on the basis of which alone it could be in a position to continue recognition of Indian medical degrees. "When the Government of India," said the President further, "is in a position to supply such guarantees by means of satisfactory reports from a Commissioner of Medical Standards and Qualifications, or from a legally constituted All-India

Medical Council, the Executive Committee . . . will give applications from Indian universities, transmitted by the Government of India, its careful and sympathetic consideration."

New Proposals from India.

In January the Secretary of State informed the General Medical Council that the Government of India was of opinion that it was not possible to reopen the question of the appointment of a commissioner in view of the strong opposition in the Assembly, and also in view of the opinion of the quinquennial Indian universities conference, which had met at Delhi in October. This conference, while favourable to the establishment of an All-India Medical Council, regarded the appointment of a commissioner as not in accordance with the best interests of medical education in India, and as wholly opposed, not only to practice elsewhere, but to the whole trend of Indian public opinion, medical and legislative.

The universities conference did, however, make the suggestion that, pending the creation of the India Medical Council, a board consisting of representatives of the Government of India and of the medical faculties of the universities should be set up as a temporary measure for determining and supervising medical qualifications and standards. The Viceroy's department, in transmitting this suggestion, regarded it as a sound one, and proposed that the board should have as its president the Director-General of the Indian Medical Service, and as members one representative from each of the faculties. It was further proposed, by the Government, that the board should appoint three inspectors, specialists respectively in medicine, surgery, and midwifery, who would report on standards of medical education and examination, and on whose reports the board would decide whether guarantees should be given to the General Medical Council that the possession of the degree of a particular university ensured the minimum qualifications required for British registration.

The Secretary of State, in forwarding these new proposals, said that it was assumed that the three inspectors would possess British qualifications, and it seemed likely that their reports, being reports of specialists in the subjects of the final examination, would be more authoritative than those of a single commissioner. Mr. Wedgwood Benn hoped that the measures proposed would be acceptable to the Council. The President could only reply that the decision of the Executive Committee at its meeting at the end of February could not be anticipated, and that the questions of the composition of the proposed temporary board and its independence and sufficiency would have to be discussed.

Meanwhile the main proposal for the eventual establishment of an All-India Medical Council has not enjoyed an uninterrupted development. An informal council of Ministers of the provincial Governments, misunderstanding the proposal as an encroachment on their control of the medical services—which, as stated, have lately been decentralized and placed in their hands—disapproved of the bill for the creation of the council, and therefore the Government of India decided for the time being to proceed no further. A later message from the Viceroy's department to the Secretary of State, dated January 6th, stated, however, "Local Governments now agree that only solution of present difficulties is to be found in the establishment of All-India Medical Council. We are most anxious to proceed with legislation with the least possible delay, but in view of intricacy of the subject and necessity of alterations in the bill, as originally drafted, to meet criticisms and suggestions received from various quarters on which it will probably be necessary to consult local Governments, it will not be possible to introduce legislative measure this session."

Some of the universities, notably Lucknow and Bombay, have expressed concern at the prospect of their medical graduates ceasing to be recognized as possessing a registrable qualification. "We find it difficult to think," writes the vice-chancellor of Lucknow, "that when the King George's Medical College has, in equipment and courses, been brought to a standard satisfactory to your inspectors who have come from year to year, the students who pass out now should be given a qualification of less value than the students who passed out in former years, especially when it is our constant endeavour to continue making further improvements."

The General Medical Council's Decision: Indian Degrees not to be Recognized.

The Executive Committee of the General Medical Council met on February 24th, and after a consideration of all the facts and representations passed a series of important resolutions, the first of which reads as follows:

> That in the absence of authoritative information respecting the medical qualifications and standards of the Indian Universities of Bombay, Calcutta, Lucknow, Madras, and Punjab, the Executive Committee of the Council, in fulfilment of its duty under the Medical Act, 1886, Section 13, is unable for the time being to recognize the medical degrees of these universities as "furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery" in this country; and that accordingly the conditional recognition hitherto granted to these degrees has now lapsed.

With regard to the Indian proposal to set up a temporary board, the Committee resolved:

> That the proposal . . . has been carefully considered by the Executive Committee; but it is unable to accept the proposal as furnishing a satisfactory method of supplying the Council with authoritative information on medical qualifications and standards in India, and with the necessary guarantees of sufficiency.

In a late message the Government of India proposed to appoint temporary inspectors of the qualifying examinations of the Universities of Rangoon and Patna. Here again the Executive Committee has found it undesirable to renew the practice of approving the appointment of separate *ad hoc* inspectors, which it had already found inadequate for the purpose of ascertaining the sufficiency of the standards for Indian medical degrees, actually required and enforced by the universities.

To separate representations from Bombay and Lucknow it was resolved simply to reply forwarding a copy of the above resolutions. There, apparently, the matter has for the time being come to an end.

ENLARGED PROSTATE AND PROSTATECTOMY.

THIRD LETTSOMIAN LECTURE BY SIR JOHN THOMSON-WALKER.*

THE concluding Lettsomian Lecture, by Sir John Thomson-Walker, on the general subject of "Enlarged prostate and prostatectomy," was delivered before the Medical Society of London on March 5th, with the president, Mr. DONALD J. ARMOUR, occupying the chair.

Suprapubic Prostatectomy.

Sir JOHN THOMSON-WALKER described the two operations for the removal of enlarged prostate—namely, that by the perineal and that by the suprapubic route. At the present time, largely owing to Freyer's advocacy, the suprapubic route was almost universally employed. Its popularity depended on the ease of approach and the readiness with which the enlarged prostate could be shelled out with the finger. It was generally believed, also, that the late results were better than those following the perineal operation.

In suprapubic prostatectomy there were two procedures at the present time—one the closed method described by Freyer, and the other the open method practised by Judd and by the lecturer himself. Freyer's method consisted in making a small incision two inches long, introducing the finger into the bladder and the forefinger of the other hand into the rectum, the abdominal walls being depressed by the knuckles. Judd's method was described in the *Proceedings* of the Mayo Clinic, but it was a short description, and it was not easy to know exactly all the details. The method the lecturer himself practised was to make a long incision, about five inches; the forefinger was passed into the bladder, and enucleation took place by the same method as employed by Freyer. The patient was

* Sir John Thomson-Walker's two previous lectures were reported in the *British Medical Journal* of March 1st (p. 422) and March 8th (p. 451) respectively.

then placed in the Trendelenburg position, and the retractor introduced into the bladder, the bladder base being freely exposed. Haemorrhage was controlled by suture and packing with gauze. All shreds and flaps were removed; a large opening was provided between the bladder and the prostatic cavity and a rubber tube introduced. Very careful post-operative treatment was carried out, an important part of which was constant irrigation with weak solution of silver nitrate. The tubes were removed on the fifth day, and the catheter on the seventh day, but the latter was reintroduced if urine was not passed by the twelfth day. If haemorrhage still threatened, the catheter was repacked with gauze.

The lecturer said that he had already discussed, in his second lecture, the nature of the fibrous prostate. In most of such cases enucleation by the closed method was a difficult and unsatisfactory operation, and it might be impossible to complete the enucleation by that means. The ultimate results were highly unsatisfactory in the majority of cases. The ragged walls which were left promoted sepsis, and post-operative contraction of the outlet of the bladder was a likely sequel. In many cases the fact that the prostate was adherent was not discovered until the operation had begun, and occasionally not until the prostate was partly enucleated. He found no difficulty at all, on the other hand, in dissecting out adherent prostates by the open suprapubic method.

Surgical Accidents and Failures.

A list was shown on the screen of the cause of death in 269 cases at St. Peter's Hospital, where suprapubic prostatectomy had been done for simple enlarged prostate.

Surgical accidents (shock, cardiac failure, haemorrhage)	64
Renal failure (uraemia)	67
Septic complications (pyelonephritis, pelvic cellulitis, etc.)	63
Diseases of lungs (pneumonia, bronchitis)	28
Diseases of circulation (cerebral haemorrhage, coronary thrombosis, venous thrombosis, pulmonary embolism)	26
Diseases of bowel (acute dilatation of stomach, etc.)	3
Asthenia and general debility	10
Various (acute mania, influenza, pancreatitis) ...	8

As for the merits of the two operations, the closed, blind, or Freyer method had the advantage of rapidity, which in some cases was a matter of importance. The rapidity must, of course, depend on the skill of the surgeon, but, other things being equal, this was the most rapid of the suprapubic methods. The operation was, moreover, easier to perform. Once the surgeon had learned to find the line of cleavage he would succeed, in some measure at least, in removing the obstruction. The disadvantage was that sepsis was more likely to occur, haemorrhage was not so easily controlled, and post-operative obstruction might be expected. The open operation had the advantage that many causes of sepsis were removed or avoided, haemorrhage was efficiently controlled, and post-operative contraction more effectively guarded against. Its disadvantage was in its greater difficulty, and a knowledge of bladder surgery was necessary.

Mortality of the Operation.

In order to obtain a general view of the mortality in suprapubic prostatectomy the lecturer had collected statistics from various sources representing the different conditions under which the operation was performed. These included statistics from eleven general hospitals in different parts of the country for the last ten years and one hospital for seven years. The statistics for these twelve hospitals in cases in which operation had been performed for simple enlargement of the prostate were as follows:

Total operations	3,451
Total deaths	675 (19.5 per cent.)
One-stage operations	2,060
Deaths	424 (20.5 per cent.)
Two-stage operations	1,234
Deaths	215 (17.4 per cent.)

The figures for St. Peter's Hospital, London, a special hospital devoted to this class of case, during a period of twenty-nine years, showed that there had been 2,691 cases, with 268 deaths, a mortality of 9.9 per cent. The fluctuations of the mortality in different years were remarkable, which illustrated the fallacy of taking only a short period of time or relatively a few cases on which to estimate results. In the lecturer's private practice, for the eleven years 1919–29, he had performed suprapubic prostatectomy on 472 cases of this description, with 25 deaths, a mortality of 5.2 per cent. The total number of private cases was 608, with 37 deaths, a mortality of 6.08 per cent.

General Hospitals, Special Hospitals, and Private Experience.

He thought it was the experience of all surgeons that there was a very considerable difference between the mortality in their private practice and in their hospital work. There was a further difference between the mortality following prostatectomy carried out in the wards of a special hospital and in the wards of a general hospital. Evidently there was some factor at work outside the immediate control of the surgeon which produced so constant a difference in mortality. Before operation the patients seen in private practice were, on the whole, better cared for and subjected to less physical strain and less exposed to effects of unsuitable diet than hospital patients. Further, hospital patients as a rule were submitted to operation at a later stage of the disease, and infection of the urinary tract was rather more frequently present in them than in private patients. The principal cause of the difference in the statistics was to be found in the different conditions under which post-operative treatment was carried out in a general hospital, a special hospital, and private practice. In a general hospital the patients were necessarily treated in large freely ventilated surgical wards, and the post-operative care was in the hands of the resident surgeon. The private patients were in special homes, and the post-operative treatment was carried out by the operating surgeon or his permanent assistant. Between these was the special hospital, where the grouping of cases led to special measures in regard to nursing, and where the post-operative treatment was in the hands of a specially trained officer.

Preparation of Patients and After-Care.

There were two other points on which he spoke with some diffidence because they related to matters of surgical opinion rather than to the discussion of general management. He was not certain that sufficient attention was paid to the complete examination and careful pre-operation treatment of these cases, or that the measures taken to combat post-operative sepsis and haemorrhage were universally adequate. With regard to the influence of the type of operation on the death rate, the list he had quoted showed, for a total of 2,060 single-stage operations, a mortality of 20.5 per cent., and for 1,234 two-stage operations a mortality of 17.4 per cent. In St. Peter's the mortality for the two-stage operation was slightly higher than for the single-stage. If these figures were taken at their face value they were misleading in any comparison of the two procedures. Where the single-stage operation was the rule, the two-stage operation was reserved for the more serious cases, and was naturally accompanied by a higher mortality. It appeared that in general hospitals where the whole of the cases were operated on in two stages, there was a moderate improvement in the death rate. His own preference was in favour of a more careful and prolonged preparation, with a single-stage operation, and more careful instruction in post-operative treatment in these cases.

The operation might be said to have failed or to have been incompletely successful when free voluntary micturition was not re-established or when frequent micturition and bladder retention were not relieved, or when there were recurrent attacks of cystitis and similar conditions, or the development or recurrence of stone, or where the wound did not close. These failures could be traced to two causes—namely, sepsis and obstruction. In his own series of private cases the day at which urine was passed after operation averaged from the tenth to the thirteenth, and the average day at which the wound was dry was the sixteenth.

At the conclusion of the lecture a cinematograph demonstration of open prostatectomy was given, with Sir John Thomson-Walker as operator. The photographic work was that of the medical department of Kodak, Ltd. A description of this film when it was first shown before the Royal Society of Medicine appeared in the *British Medical Journal* (July 6th, 1929, p. 23).

Scotland.

Vital Statistics of Scotland.

THE quarterly return of the Registrar-General for Scotland, dealing with the quarter ended December 31st, 1929, and including a supplementary return for the whole year 1929, has just been issued. Vital statistics show that the birth rate has fallen, being the lowest on record, while the death rate is higher than those of the preceding six years. This rise is attributed to a severe epidemic of influenza in the early months of the year. The birth rate of the year was 19 per 1,000, or 0.8 less than that of the previous year, and 1.7 less than the quinquennial mean. The marriage rate was slightly higher than that of the previous year. The death rate was 14.5 per 1,000, which is 1.2 more than that of the previous year, and 1.0 more than the quinquennial mean. The infantile mortality rate was 87 per 1,000 registered births, which is 1 above that of the previous year, but 2 less than the mean of the preceding five years. Death rates from tuberculous diseases and from tuberculosis of the respiratory system both show further reduction, being the lowest yet recorded. Those who died from malignant disease numbered 7,107, which is the largest number recorded as yet in any one year, being 206 more than that of the previous year. The death rate for the principal epidemic diseases was slightly below that of the previous year. With regard to the statistics of the quarter, births numbered 21,998, which was 1,405 less than those of the fourth quarter in the previous year. The number of deaths registered during the fourth quarter was 15,353, or 2,070 more than those in the third quarter, but 506 less than those in the fourth quarter of the previous year. The death rate for the quarter was 12.4 per 1,000, the lowest fourth quarter death rate yet recorded, despite the fact that the death rate for the year had risen. The figures for the causes of death during the quarter show that 3.5 per cent. were attributable to the principal epidemic diseases. Deaths from epidemic diseases, other than those grouped under the principal diseases, included 40 from cerebro-spinal meningitis, 24 from encephalitis lethargica, and 38 from erysipelas. There were 130 deaths from diseases and accidents of pregnancy, or a mortality rate of 5.9 per 1,000 registered births, which is 2.5 less than that of the fourth quarter of the previous year.

Installation of Glasgow Chancellor.

In succession to the late Lord Rosebery Sir Donald MacAlister was installed on March 4th as Chancellor of the University of Glasgow. Sir Donald was Principal of the University for twenty-two years and retired last October. Principal R. S. Rait presided at the commencement of the ceremony, and the new Chancellor took the chair after the administration of the oath. Among those upon whom he conferred the degree of Doctor of Laws were Sir George Newman, Chief Medical Officer of the Ministry of Health, and the new Principal and Vice-Chancellor of the University of Glasgow. In his address the Chancellor referred to the Glasgow School of Theology, which included both the University Divinity School and the Trinity College of the United Free Church. These would now be united as a result of the recent union of the Churches.

Presentation to Professor G. M. Robertson.

On March 7th Professor George M. Robertson, superintendent of the Royal Edinburgh Hospital for Mental Diseases, was presented with his portrait at a dinner held in the Hall of the Royal College of Physicians, Edinburgh. Lord Provost Whitson presided. The presentation was made by Mr. T. M. Gardiner, chairman of the Board of Managers, who paid a tribute to Professor Robertson's exceptional ability.

Forthcoming Visit of the Prince of Wales to Edinburgh.

The Prince of Wales will visit Edinburgh on June 12th in connexion with the bicentenary of the Royal Infirmary, which took place last year. The chief purpose of the visit is to assist an appeal for funds to extend the institution. The foundation stone of the present buildings was laid in 1870 by King Edward VII, then Prince of Wales. The proposed extension, which will cost approximately £300,000, will provide a gynaecological and maternity hospital, a new nurses' home, and other buildings, to be erected on the neighbouring site of George Watson's College. His Royal Highness will also visit Murray House, Moredun, on the outskirts of Edinburgh. This home has 20 beds for sailors and soldiers who were disabled in the war but are not bedridden.

Edinburgh Medical Officer of Health.

The Edinburgh Town Council, on March 6th, discussed the appointment of a successor to Dr. William Robertson, M.O.H. for Edinburgh, who retires this year. Thirty members voted to confine the election to officers already in the service of the Town Council, and thirty voted for an open appointment. The Lord Provost gave his casting vote in favour of advertising the post. It was intimated that a new scheme, drawn up by Dr. W. Robertson, for the Public Health Department, would be circulated.

Waiting List at Royal Infirmary, Edinburgh.

The report of a special committee, appointed to consider the waiting list of the Royal Infirmary, Edinburgh, states that the list is revised every three months, and that 2,419 patients are at present waiting for admission. According to the report of the Mackenzie Committee, there was a deficiency in Scotland of about 3,000 beds, and the committee is of the opinion that about 870 represents the proportion in its own area. Although the Infirmary to-day is working at full pressure the committee is satisfied that no patient requiring immediate attention is ever refused admission. Every applicant who has been on the waiting list for more than three months receives a personal communication, and if he no longer desires admission, or has been treated elsewhere, or if no reply is received within a fortnight, his name is removed from the list. Between 400 and 500 names are removed every quarter for these reasons. Only a small percentage, never exceeding 20 per cent. of the names on the list at any quarterly revision, were found to have been waiting admission for six months or over. Current cases on the list are classified, graded, and starred for priority in treatment. Nearly four-fifths of the total number are surgical cases. The committee recommends that one of the male wards should be converted into a female ward, because of the larger number of female patients. It is pointed out that the gradual extension of the Astley-Ainslie Convalescent Institution, and the radium institute at Beechmount, when completed, will help to solve the problem. A substantial reduction, however, depends on carrying out the proposals that have been made for extending the Infirmary.

Leith Hospital.

According to the annual report of the Leith Hospital there were 2,078 in-patients during 1929, an increase of 134 on the previous year, and 18,734 out-patients; 1,269 patients were also treated in the children's wing. The ordinary income for the year amounted to £17,357, and the ordinary expenditure to £18,251, while the extraordinary income was £2,806 and the expenditure £664. At the annual meeting the chairman remarked that in the past twenty-one years expenditure had risen gradually from £6,000 to £18,000, with the growth of special departments, and the continual demand for fuller service. The purchase of ground for future extension in the neighbourhood of the hospital was under consideration.

Royal Public Dispensary, Edirburgh.

The annual report of the Royal Public Dispensary, Edinburgh, points out that the helpful and philanthropic medical work of this dispensary had been carried on since the year 1776 in the densely populated district of the Pleasance and surrounding neighbourhood. Baillie G. D. Brown, who presided at the annual meeting, remarked that the number of new patients attending the dispensary last year was 832, while 302 had been treated by medical students under the supervision of the medical officers in their own homes. An important recent branch of the activities of the dispensary was child welfare work, in which excellent service was being rendered. It was added that the finances of the institution were in a sound condition.

England and Wales.

Medical Society of London.

THE 157th anniversary dinner of the Medical Society of London, held on March 6th at the Hotel Cecil, was noteworthy for the number of distinguished Canadian guests who attended in honour of the president, Mr. Donald Armour, senior surgeon to the West London Hospital. These included Colonel the Hon. J. L. Ralston, Minister of National Defence, the Hon. Lucien Pacaud, acting High Commissioner for the Dominion, Sir George McLaren-Brown, European General Manager of the Canadian Pacific Railway, Mr. C. J. Smith, Vice-President of the Canadian National Railways, and Mr. William C. Noxon, Agent-General for Ontario. Other guests at the high table were Dr. Hamed Mahmud, Egyptian Chargé d'Affaires, the President of the Royal College of Physicians, the Regius Professors of Medicine at Oxford and Cambridge, the Master of the Society of Apothecaries, the medical heads of the Navy, Army, and Air Force, the President of the British Medical Association, the Editors of the *Lancet* and the *British Medical Journal*, and the presidents of kindred medical societies. The after-dinner speeches were few and short and good. Sir Humphry Rolleston gave the toast of "The Medical Society of London" in a few graceful words. The President, in reply, touched on the progress of the Society along peaceful lines after its early dissensions, growing yearly in strength and stature, and always adhering to the purposes of its foundation as laid down by Lettsom in these words: "The institution of this Society is to give the practitioners in the healing art frequent opportunities of meeting together, and conferring with each other, concerning any difficult or uncommon cases, which may have occurred; or communicating any new discovery in medicine, which has been made, either at home or abroad." The Society, said Mr. Armour, still prided itself upon what might be called, professionally speaking, the cosmopolitan character of its meetings. Unlike its rebel offspring, now grown to Gargantuan proportions under the name of the Royal Society of Medicine, its Fellows were not "sectionists"; they did not work in watertight compartments; they did not encourage specialism as such. To its most carefully selected and jealously guarded list of Honorary Fellows a single addition had been made this year, the first in three years. Sir Arthur Keith's absence in Egypt, seeking health, and perhaps new problems to elucidate, prevented him from being present that evening, but they anticipated with the greatest pleasure his oration before the Society in May, on "Modern medicine and evolution." The health of "The Guests" was adroitly proposed by another past-president, Dr. Eustace M. Callender, and Colonel Ralston, who responded, told several new stories and expressed the pleasure felt by himself and his fellow countrymen in dining with the oldest London medical society under the presidency of the first Canadian to hold that office.

A London Post-Graduate Course in Mental Deficiency.

In co-operation with the Central Association for Mental Welfare, the University of London has arranged a course of lectures on mental deficiency and allied conditions, supplemented by clinical instruction. It will be held at the University, Imperial Institute Road, S.W.7, and be based on the requirements for the diploma in psychological medicine; it is intended more especially for medical practitioners who are engaged as school medical officers, certifying officers to local authorities under the Mental Deficiency Act, medical officers of institutions, and others definitely concerned with the care of subnormal or abnormal persons. The course will consist of two parts, the first occupying the week May 5th to 10th. Dr. A. F. Tredgold will deliver seven lectures on the nature and pathology of mental deficiency, its etiology and classification, the characteristics of aments, clinical varieties, moral deficiency, and differential diagnosis. Dr. F. C. Shrubsall will give three lectures on the administrative procedure in the ascertainment and treatment of the mentally defective; Professor Cyril Burt will lecture twice on the psychology of mental defectives; and Dr. Norwood East will give one lecture on crime and mental defect. Clinical work will be arranged in the form of visits to special schools for mentally defective children, and to residential institutions in or near London; there will also be clinical demonstrations. The second part of the course extends from May 12th to 17th. Two lectures will be given by Professor Burt on general psychology, and three by Dr. Tredgold on the borderland of mental deficiency, and Dr. Bernard Hart will discuss degenerative processes and associated types of delinquency. Dr. E. O. Lewis will give a lecture on the incidence of mental deficiency; Miss Lucy G. Fildes three lectures on educational disabilities; and Dr. Shrubsall three lectures on encephalitis lethargica, causes of retardation other than mental defect, and the value of social inquiry in relation to the defective or maladjusted child. Clinical work will be arranged in the form of visits to hospitals and clinics, and attendances at case conferences. Either course may be taken separately, and applications must be sent to Miss Evelyn Fox, c/o University Extension Department, University of London, South Kensington, S.W.7, by April 14th. The registration fee is 10s. 6d., and a fee of three guineas is payable for either part of the course. The fee for the whole course is £5 15s. 6d.

Ireland.

National Health Insurance in the Free State.

IN a recent discussion in the Dail on a vote for £2,621 to complete the sum necessary to defray the expenses of the National Health Insurance Commission, General Mulcahy, Minister for Local Government and Public Health, referred to the increased expenditure on sickness and other benefits. The number of insurances, he said, had increased more rapidly than had been anticipated. On being asked whether medical certification could not be arranged on a county instead of on a dispensary basis, General Mulcahy replied that he had failed, so far, to reach an agreement with the medical profession, which had rather reluctantly consented to the repayment to the Treasury of the extra amount entailed by dispensary certification. The sum of £800 had been fixed by the Ministry of Finance to be paid to the Treasury for the year under review. The Minister has been misinformed. No consent has been given by the medical profession to an agreement for reimbursing the Treasury of the extra amount required to administer the certification grant on a dispensary basis.

Sligo Mental Hospital.

At the last meeting of the Committee of Management of the Sligo and Leitrim Mental Hospital the following letter from the Appointments Commission was read:

"In compliance with the statutory request received under Section 6 (2) of the Local Authorities (Officers and Employees) Act, 1926, in connexion with the above-mentioned position (Resident Medical Superintendent, Sligo District Mental Hospital), I am directed by the Local Appointments Commissioners to state that they recommend Dr. John Dunne, Grangegorman Mental Hospital, Dublin, for appointment to the position. A summary of the recommended candidate's qualifications is given hereunder."

After long discussion a resolution was passed unanimously, declaring that the Appointments Commissioners had no right to send a doctor appointed by them without consulting the committee representing the ratepayers of Counties Sligo and Leitrim, and that in the considered opinion of that committee Dr. Thomas Gilgriest, who has filled the position of assistant resident medical superintendent for thirty-three years with credit and distinction, should be elected. The committee, therefore, requests the Department, before accepting the recommendation of the Appointments Commissioners, to give a full statement of the reasons for refusing to sanction promotion under Section 5, and a more detailed statement of the findings which guided them in this selection. In connexion with this dispute the contention of the hospital committee that Dr. Gilcriest should be promoted to the office of resident medical superintendent has a good deal of support from lay and medical opinion. The Local Authorities (Officers and Employees) Act, 1926, makes provision for promotion

subject to the sanction of the Minister for Local Government and Public Health. The Minister, however, in the recent vacancies in Clonmel and Sligo, refused his sanction of the promotions recommended by the asylum committee of the assistant medical officers in the mental hospitals in which the vacancies occurred, and directed that the offices be filled by recommendations made by the Appointments Commissioners through the means of selection boards. The selection boards are debarred by statute from confining their selection to the assistant medical officers of the institutions in which the vacancies occur, and must take into account the claims of all qualified applicants, which include those of a number of assistant medical officers from other mental hospitals. Prior to the passing of the Act creating the Appointments Commission and the selection boards, the senior medical assistant was almost invariably promoted by the asylum committees to the office of medical superintendent when it became vacant.

Presentation to Dr. W. W. Murphy.

On his retirement, after thirty years' service, from the honorary secretaryship of the County Wexford Medical Practitioners' Association, Dr. William W. Murphy of Coolgreaney was entertained at dinner by the members of the association, and presented with an ornamental clock. Dr. Murphy has taken a very active interest in the welfare of the medical profession in all parts of Ireland. He is chairman-elect of the Irish Committee of the British Medical Association; he is also a member of the Irish Medical Committee and Irish Medical Association.

Correspondence.

PEPTIC ULCER.

SIR,—In my article in the *Journal* of March 8th, the word "gastro-enterostomy" on page 460, line 6, should read "*gastro-gastrostomy*."

May I suggest that Mr. Norman Lake (p. 466) rather spoils my aphorism? He quotes, incorrectly, "Statistics may be made to prove anything, even the truth." In its original form this read "Statistics may prove anything, even the truth." I intended to indicate an inherent vice in statistics, not to impute corruption to their compiler! So my aphorism is not "cynical": and for cynicism I have no talent.—I am, etc.,

Leeds, March 8th. MOYNIHAN.

SEX HORMONES OF THE ANTERIOR PITUITARY.

SIR,—A considerable amount of publicity was provoked by the recent announcement by the dean of the Faculty of Medicine of McGill University concerning the successful extraction by Professor Collip of a substance in crystalline form from the human placenta which exerts a very profound influence upon the ovary. In the official announcement it was stated that this success marked the final stage of a long series of experimental studies carried out by many workers in different countries, and generous acknowledgement was paid to the contributions of my colleague Dr. B. P. Wiesner. Since in certain accounts which have appeared in this country erroneous statements seem to have been made, it appears to us desirable that the facts of the matter as we see them should be set forth.

It has been established for a long time now that the elaborated products of the anterior lobe of the pituitary exert profound influences on growth, on the incitement and on the inhibition of oestrus and so forth, and the influence of the pituitary on the ovary has commonly been referred to the action of the sex hormone of the anterior pituitary. Dr. Wiesner and I, in 1928, endeavoured, we think successfully, to show that the relation of anterior lobe and ovary is by no means so simple, and that in order to accommodate all the facts that have now been demonstrated, it is necessary to postulate the existence of two gonadotrope factors in the anterior lobe. Since then, further work on these two factors has been continued, and the results have been reported on several occasions. Moreover, extracts containing these factors have been supplied for use in clinical practice, and in due course those clinicians who have used them will record their conclusions in appropriate journals. But, of course, from our point of view, this clinical application was regarded as being essentially experimental, and we have been eagerly and, it may be said, confidently awaiting the conclusions derived from clinical experience.

In view of the fact that such tentative reports as we have received have been definitely encouraging, Dr. Wiesner, who attended the Physiological Congress at Boston and gave a demonstration of this work, drew Professor Collip's attention to it and to its promise. We regard it as exceptionally fortunate that Professor Collip should have been attracted to this particular field, and particularly that he should have thought it worth while to extend the work. Naturally, we have read with the greatest possible interest the preliminary account given by Professor Collip in the *Canadian Medical Journal*, and we eagerly await the publication of the details of his methods of preparation. For, from the paper that has appeared, it is quite impossible to gather whether the substance which he has isolated represents the oestrogenic or the kyogenic factor, and, what is even more interesting to ourselves, whether the hypothesis concerning the duality of the sex hormone of the anterior pituitary which we have adumbrated is correct or otherwise.

There is one point in Professor Collip's paper which is puzzling, for he seems to have found it desirable to abandon the use of sulphosalicylic acid for the reason that he found it a barrier to further purification. In this department, Wiesner and Patel have elaborated methods which remove and recover this agent, and the methods now in use have given us extracts of greatly increased purity and potency. Reports concerning the experimental and clinical use of these extracts will appear in the near future. Now that work on these substances is being prosecuted on both sides of the Atlantic, it may be expected that great advances in our knowledge of their nature and in the usefulness of their application will be made.—I am, etc.,

F. A. E. CREW.

Animal Breeding Research Department, University of Edinburgh, March 16th.

TYPES OF ACUTE MASTOID INFECTION.

SIR,—To Mr. Wright's instructive list of acute mastoid infections (March 8th, p. 437) I should like to add the form described by Gruber (*Diseases of Ear*, translated by Law and Jewell, 1890, p. 407), and by Lue (*Transactions* of the Ninth International Otological Congress, Boston, 1912, p. 194). Lue calls it "sub-periosteal temporal abscess of otic origin without intra-osseous suppuration." There is extreme displacement of the auricle downwards and forwards, and bulging of the upper wall of the external meatus. Gruber formulates the rule that "abscesses in the neighbourhood of the upper third of the auricle are to be opened from the external auditory canal, unless any special circumstances should indicate another situation." The observance of this rule may, as Lue says, spare our patients the useless opening of the bone. I have had at least two cases which bore out the conclusions arrived at by Gruber.—I am, etc.,

London, W.1, March 16th. JAMES DUNDAS-GRANT.

DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.

SIR,—In the *Journal* of March 1st Dr. W. Arnott Dickson, in his excellent address on the diagnosis and treatment of pulmonary tuberculosis, deals very drastically with the Pirquet tuberculin skin reaction. After a sufficient trial of the test, both in children and in adults, he declares that it is "for diagnostic purposes of no value whatever. . . . In known cases of tuberculosis the test was negative in almost as many cases as it was positive." In contrast to this opinion and experience, he refers to some remarks of mine on the subject in the *Journal* of October 12th, 1929, as "a panegyric of the test" qualified by my admission that it "may . . . fail to appear in an actually tuberculous condition."

This airy phrase, and the seriously incomplete quotation of my words (the two words "although rarely" being omitted), give a very misleading impression of what I said.

In the article referred to I was dealing not with pulmonary tuberculosis, but with all forms of the disease in childhood. The gist of a short paragraph dealing with the matter was that it was an extremely delicate test of tuberculous infection, and if properly performed seldom failed even in advanced and acute disease; that in the first two years of life it had great diagnostic value; that in later childhood a positive test only permitted a "tuberculous" interpretation of the evidence, and had not even corroborative value, but that a negative result of the test was of great value at all times in excluding tuberculous disease.

Dr. Dickson and I are probably agreed that a positive reaction means the existence of a focus of tubercle; but that it gives no information as to the extent, activity, and site of that focus, and has therefore a very limited diagnostic value. But we differ greatly in regard to our experience of failure of the test in what he calls "known cases of tuberculous disease"; in such cases he has had many failures, while I have had very few. The principal value of the test is when, having been performed by a correct technique, it is negative; in such cases tuberculous disease can be excluded.—I am, etc.,

Edinburgh, March 7th. CHARLES MCNEIL.

SIR,—In his interesting paper on the diagnosis and treatment of pulmonary tuberculosis, Dr. Arnott Dickson makes some remarks on diagnostic tests, but, curiously enough, he entirely omits any mention of the only tuberculin test which is now commonly held to have any real diagnostic value—namely, the subcutaneous test.

There is no need to enlarge on the futility of the von Pirquet test in any but infants, for this has long since been established, but it has always been an enigma to me why more use is not made of the subcutaneous test in adults or adolescents. Clive Riviere, writing in 1921, in the third edition of *The Early Diagnosis of Tubercle*, states—speaking of the practitioner: "At the outset he must know that the value of any particular tuberculin test is no longer a matter of opinion, but one of ascertained fact. For an enormous mass of material, gathered from all quarters, is now to hand as a standard, the results of every form of test on every form of tuberculosis, and also on the healthy. Such material, when sifted, admits, in most cases, of but one interpretation. It is, therefore, no longer open to any individual to say, 'I believe in this or that tuberculin test in diagnosis,' unless his belief is supported by these incontrovertible facts. . . . No one, to take a concrete example, can in these days rely on a positive von Pirquet reaction as evidence of active tuberculosis in the adult and retain our respect for his intelligence; a vast mountain of fact is against him."

But the subcutaneous test stands on other ground. Though of small value on the positive side, it is of the greatest value on the negative side; and, after all, in the really doubtful case, what greater satisfaction can there be than to be able to send away the patient with the assurance that he has no active tuberculosis? No doubt a large proportion of cases will give a positive reaction, leaving the diagnosis still in question; but the small proportion of negative results is enough to justify the use of the test. To quote Riviere again: "A negative result furnishes strong evidence against the presence of active disease"; and again, "There is general agreement on the value of a negative subcutaneous test in suspected early or slight disease."

It is, of course, understood that the subcutaneous test should only be undertaken in the absence of contraindications. Koch's rule was that "Patients with temperatures over 37° C. (98.6° F.) in the axilla are unsuitable for the diagnostic administration of tuberculin, and should under no circumstances be submitted to the tuberculin test." Riviere says: "A careful three- or four-hourly record [of temperature] must be kept for some days before the injection, which should be abandoned if the temperature rises above 99.2° F. in the mouth, or 99.8° F. in the rectum"; but even this is *running* the risk of a dangerous focal reaction. The test is therefore strictly limited in its applicability.

With reference to Dr. Dickson's remarks on the treatment of tuberculous empyema, I should be interested to hear whether surgeons who specialize in thoracic surgery are agreed that it is good treatment to withdraw the purulent effusion and wash out the pleural cavity with weak iodine solution as advocated by Dr. Dickson, the lung afterwards being kept collapsed by air. I have no experience of such cases, but should imagine that the proceeding would not always be easy to carry out, nor without danger. But, of course, the condition is desperate.—I am, etc.,

London, S.W.5, March 3rd. E. WEATHERHEAD, M.B.

SIR,—Dr. Arnott Dickson in his lecture (*Journal*, March 1st, p. 379) states that "ultra-violet light, the panacea of the moment, is of very problematical value in lung tubercle." It would be of great value and interest to know whether Dr. Dickson bases this opinion on his own observations. At the second international conference on light and heat in medicine and surgery I gave an analysis of 123 cases of chronic pulmonary tuberculosis treated with ultra-violet light. Some of these had done extremely well. Wood published a series of cases in the *Lancet* (August, 1926), and a number of authors, including Lo Grasso, have claimed good results in America. Does Dr. Dickson's experience not bear out these claims?—I am, etc.,

London, W.1, March 4th. M. WEINBERG.

THE ETIOLOGY OF DENTAL CARIES.

SIR,—No excuse surely is necessary for the intrusion of a practising laryngologist into a correspondence upon dental caries. If, however, any be called for in my own case, it is to be found in the fact that I have been looking into the mouths of a whole generation of the English race—that race with the unhappy distinction of having the worst teeth on earth—and that I find those teeth to be little, if any, less carious to-day than they were when I began my long-continued inspection thirty years ago. True, they are better cared for nowadays by the dentist, as the fillings and the gaps in the ranks show; but the disease itself, although its havoc is now being restrained, does not seem to be much, if any, less prevalent than it used to be. And this is surely a disturbing and regrettable fact.

Those of us who, for many years past, have been following with interest Dr. J. Sim Wallace's patient and painstaking work are well aware of his claim that, if certain dietetic rules were generally observed, dental caries would be greatly reduced, if not, indeed, entirely abolished. The matter, of course, is one pertaining to the public health, and so I am impelled to ask why the public health authorities of Britain have been so hesitant in undertaking the instruction of the people upon this important detail. I understand that one or two experiments in this direction have already been made by certain medical officers of health, and, it is said, with conspicuous success. But, in spite of this encouraging result, no general movement upon national lines has, so far as I know, been made to inculcate Sim Wallace's teaching. Why is this? Have his experiments not been confirmed? Have his observations been found to be inaccurate? Have his doctrines been proved to be false?

These are not idle questions. They are questions the answers to which are of importance to every man and woman in Britain. There must be some reason, one would think, why our leading authorities have hitherto refrained from broadcasting this teaching on the prophylaxis of dental caries, and I, and I am sure many other medical practitioners, would like to know what that reason can be.—I am, etc.,

London, W.1, March 4th. DAN MCKENZIE.

DENTAL INDICATIONS OF PELVIC DEFORMITY.

SIR,—I recently published a paper (*Proceedings of the Royal Society of Medicine*, December, 1929) showing how the shape of the maternal pelvis influences both the maternal and infant mortality. I suggested, by comparison with races and peoples untouched by civilization, that the inlet of the female pelvis should be round, to match the part of the child's head, which engages in it (the sub-occipito-bregmatic circumference or halo measure), and that the oval or kidney-shaped inlet such as our textbooks depict

is always the result of rickety or osteomalacic change, due in the first place to defective diet, and then to confinement indoors with long sitting on the softened pelvis. The oval shape I believe to be pathological; it is caused by the falling forward of the sacrum between the iliac bones; the position which normally corrects this—namely, the squatting and the use of the sacro-iliac joints—has been abandoned by civilized man.

I want to go a step further. The teeth, I think, are the first to indicate the light and vitamin D deficiency; then the pelvis is affected, and last of all occurs the obvious rickety deformity seen in the legs, so that when these signs of rickets appear both the pelvis and teeth have been already damaged. On consulting the Carnegie Trust Report for 1917 I see that in districts where an open-air, natural life is lived (Shetland, Skye) the teeth are perfect, there is no rickets, and the women have easy labours, so that neither midwife or doctor is needed. On the other hand, where an indoor life begins, the town van calls with civilized food—white bread, jam, and tea—the change from the old conditions is marked, the teeth are bad, rickets is prevalent, women begin to die in childbirth, and the midwife, the doctor, and the maternity hospital become an urgent necessity. This is the case in some Highland districts, Harris, Argyle, then Glasgow.

What I am desirous of obtaining is further evidence of the interrelation of perfect teeth, the absence of rickets, easy and safe childbirth, and evidence of the converse—a high rate of dental caries and of rickets, with difficult and dangerous maternity.

I should appreciate notification of any facts bearing on this problem, and any *x*-ray studies of the pelvic inlet in the case of easy labours, showing that the sacrum does not encroach on the inlet in such people. Our canal-boat women would probably furnish the kind of evidence I want, with their open-air life and simple food. They certainly bear large families of twelve and fourteen children; they are healthy, and cannot engage either nurse or doctor at their confinements, since they are always on the move.—I am, etc.,

London, W., March 8th. KATHLEEN VAUGHAN, M.B.Lond.

RETENTION OF URINE.

SIR,—I was away at the time, and I am afraid that I missed the letter in your issue of February 15th (p. 309) written by Mr. Kenneth Walker. It is with great trepidation that I venture to reply to any criticism from one whose opinion I hold in the greatest respect, but I feel that Mr. Kenneth Walker has not quite appreciated that I used the words "a fine needle," whereas he refers to a "trocar." The withdrawal of a cannula might quite well lead to leakage into the cellular tissue of the space of Retzius; but this is not likely to follow the withdrawal of a fine needle unless the bladder be as thin as parchment, which is surely an uncommon state of affairs in cases of stricture, the bladder wall usually being thicker than normal in these cases due to hypertrophy.—I am, etc.,

Hove, March 7th. H. J. MCCURRICH.

APPLICATION OF GAMMA RAYS TO DEEP-SEATED TUMOURS.

SIR,—Professor J. Joly, in the *British Medical Journal* of March 8th (p. 466), describes a method which was used several years ago by the late Dr. Robert Knox at the Cancer Hospital, Fulham Road, London, for the application of *x* rays to a deep-seated tumour. He not only devised a method for the rotation of the source of rays, but also one in which the tube was stationary and the patient rotated with the couch. In some respects the method has not the value of that of several ports of entry.—I am, etc.,

Leeds, March 10th. LEO A. ROWDEN.

SIR,—When I was honorary assistant in the *x*-ray department at the Cancer Hospital, London, an apparatus similar to that described by Professor Joly was constructed in 1913 or 1914, under the supervision of the late Dr. Robert Knox. The patient was placed upon a couch in the horizontal position, and, the *x*-ray tube being fixed to the periphery of a wheel above the couch, the beam of rays was so directed that the central ray was focused upon the deep-seated tumour. The wheel, with the attached *x*-ray tube, was then rotated by means of a small electric motor, describing a continuous circle, the central ray thus taking a conical path. The skin surface of the patient was protected in such a way that entry of the rays was only permitted in a narrow circular path. The method was given an extensive trial and it worked successfully, but the therapeutic results were not considered to be in any way better than when irradiation through multiple ports in the ordinary manner was employed. The apparatus was cumbersome; it was difficult to calculate accurately the dose delivered, and the revolving tube was a source of annoyance to the patient.—I am, etc.,

London, W., March 7th. CHRISTOPHER KEMPSTER.

ANAESTHETICS IN MIDWIFERY.

SIR,—May I be allowed to contribute to your correspondence on this subject?

I think few people would deny that, whatever the reason, very few poor mothers do actually enjoy "the blessings of an anaesthetic." Why is this? Undoubtedly the question of expense *is* of the first importance. At one institution, renowned over the world for its midwifery, cases of normal labour are given chloroform at the end of the second stage only if they have come in as "staff" cases of the resident doctors and paid a fee. Would not a contribution from the Baldwin-Dawson fund increase the numbers enjoying "the blessings of an anaesthetic" there?

I venture to think that if, for example, the local authority paid even a guinea to practitioners for each anaesthetic given during labour, the number given would tremendously increase: at present, however, midwifery is generally poorly paid. Even in middle-class practice not a few cases of normal labour are delivered without any attempt being made to mitigate their pains; and in one town, not a hundred miles from here, I am told that it is a common practice to apply the forceps without an anaesthetic.

My experience as a resident obstetric officer was very similar to Dr. Bodman's. By using students for the purpose as well as myself, and continually insisting on the necessity of an anaesthetic, I managed to have about half the normal cases anaesthetized *à la reine* over a period of several months. But the administration of an anaesthetic throughout the second stage takes time, and often interferes with the anaesthetist's other work, his sleep, or his meals, so that unless he is almost continually spurred from within or without to do it, it is not done. I am quite sure that unless the resident staffs of maternity hospitals are considerably increased it will not be possible to give every patient an anaesthetic. Resident anaesthetists, with no other duties, should be appointed. This can be brought about by means of the Baldwin-Dawson fund.

I am also convinced, largely for the same reasons as Dr. Bodman, that anaesthesia is desirable in nearly every case; and I happen to be one of those apparently unusual people who cannot bear a woman crying out in labour without wishing to relieve her pain.

Dr. Rowland alludes to "misdirected enthusiasm in matters medical," and Dr. Hamilton to the "absurdity" of the appeal. Should it not be the natural aim of every husband to ensure that his wife goes through labour with the minimum amount of pain? Not a subject, this, merely "for the classroom or the medical press."—I am, etc.,

Leeds, March 8th. A. M. CLAYE.

SIR,—I should be grateful if you will allow me, as a layman, to reply to the letter of Dr. F. M. Rowland in the *Journal* of March 1st (p. 414), presumably inspired by Mrs. Stanley Baldwin's appeal to provide anaesthetics for women in childbirth. It will certainly be surprising to Mrs. Baldwin, and to many others, to learn from Dr. Rowland that anaesthetics are invariably available under the existing machinery of the Midwives Act for the poorest mother, either in her own home or in an institution. If this were the case the appeal would undoubtedly be un-

necessary and the funds already subscribed would have been given under a misapprehension. Unfortunately anaesthetics are not available in the cases mentioned by Dr. Rowland. The majority of the poor are not attended by a doctor but by a midwife, and it is obviously impossible for the midwife, when dealing with a case single-handed, to administer the anaesthetic and effect the delivery simultaneously. In those comparatively rare cases where a doctor is called in, it is usually due to a complication where the use of an anaesthetic is imperative.

So far as maternity hospitals and institutions generally are concerned, it is true that anaesthetics are used in connexion with certain deliveries, but replies obtained from the majority of these institutions show definitely that the giving of the anaesthetic for normal deliveries—and this is the basis of Mrs. Baldwin's appeal—is the exception rather than the rule. The reason is practically always the same—institutions and hospitals have not the funds available for paying the salary of a resident anaesthetist or anaesthetists. The general public does not realize that in large maternity hospitals, such as Queen Charlotte's for instance, babies are born at all hours of the day and night, and that consequently one resident anaesthetist is unable to cope with the work. Two at least are essential, and it is for this reason that one may be sure of hearty public support, and institutional approval, of Mrs. Baldwin's campaign.—I am, etc.,

DIGBY C. H. D'AVIGDOR.

Queen Charlotte's Maternity Hospital, N.W.1,
March 4th.

ANAESTHESIA FOR SHORT OPERATIONS.

SIR,—I feel bound to reply to the letter of Mr. Herbert H. Brown in the *Journal* of February 22nd (p. 362); he extols the use of *light* chloroform anaesthesia for minor operations.

May I point out that all the work of Levy and others on chloroform anaesthesia indicates that fatalities are most likely to occur by the secretion of adrenaline due to sensory stimulation under light chloroform anaesthesia. Moreover, the chloroform fatalities recorded show that a high percentage occurred during induction, or under light anaesthesia for minor operations.

The last occurrence of this kind which I noticed in the newspapers was the case of a labourer, aged 29, who was given chloroform for tooth extraction. It is chiefly those in the prime of life and of robust health who are killed by this drug, and I do not believe that any care, skill, or forethought can prevent the accident in those who have what is perhaps only an idiosyncrasy to chloroform. It is possible to go through life and encounter none of these patients, but the truly expert anaesthetist will not take the risk of meeting them with chloroform, because he knows that, should he be unfortunate enough to do so, skill would be useless; all he could do would be to swear before the coroner to the absolute purity of his chloroform, the exercise of his unavailing care, and the futility of his skill.

Dr. Brown might retort that he has referred to analgesia, not anaesthesia, but reflexes still exist during light anaesthesia. They certainly exist and are often exaggerated during the analgesic state, and it is possible also that these fatalities depend upon the existence of the vago-inhibitory reflex. Since ethyl chloride, gas, and ether are available it seems a great pity to trust anyone's life to luck.—I am, etc.,

F. FISHER WADDY.

Northampton, March 5th.

THE TEACHING OF ANATOMY.

SIR,—I was much interested to read in the *Journal* of March 1st (p. 373) the report of the Arris and Gale lecture on anatomy, by my old and valued friend Mr. McAdam Eccles. I sincerely hope that his lecture will be followed by an improvement in the teaching of this subject. May I add some remarks of my own, the views of a general practitioner?

Wherever possible models should be used, instead of diagrams, and models that can be handled. Some years ago I made several models for the School of Anatomy in Uganda, Central Africa (where, of course, dissecting is a difficulty), and among them a complete model of the body, except that the limbs terminated at mid-arm and mid-thigh. A skeleton was taken as a base, and the bones covered with linen; the muscles were made of felt, padded where necessary, the arteries, veins, and nerves of coloured silk of appropriate thickness, and the membranes of muslin and chiffon. With this model the position of any organ, vessel, muscle, or nerve could be seen and felt.

The more superficial muscles of the lower arm and lower limb were shown in plaster casts, corrected and painted. I know of no more useful way for a student to read up the anatomy he has learnt than by buying such casts, which are cheap, correcting their anatomy with a knife or bradawl, and painting the corrected model.

I also made a model of the nervous system, using twelve sections to show the "cord," from the crura to the lumbar region, with tin cerebral hemispheres. Silk cords passed from painted representations of parts of the body to the cerebral cortex via the sections. This enabled students to see the nerves in continuity from their origin to their termination; and the openings for the nerves being large allowed additions or corrections to be made at any time.

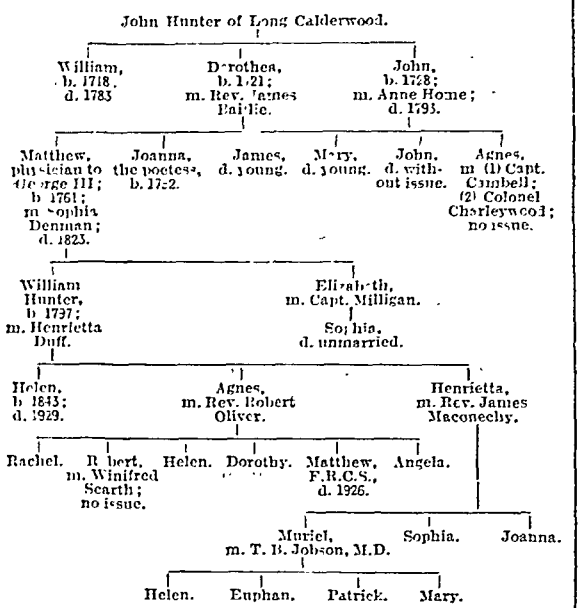
Another useful method is to practise drawing the skeleton to scale (no book gives it), and to learn the horizontal relationship of all organs and bones to the vertebral bodies, and therefore to each other. Once that has been done the different structures are seen by the scientific eye, without effort, whenever a patient is approached.

Mr. Eccles wants us to learn the movements of joints, and gives an excellent instance. But at present we cannot say of *any* joint that we are sure what muscles move it, how they move it, and which of them do not move it at certain angles. Lastly, and most important, the student should be taught to recognize bones and joints as well as other structures by their feel, in the living body. Every time he has a warm bath let him finger bones and joints until he can make out the lie and movement of every prominence and ridge and articular edge with his eyes shut. Far more useful than visible surface anatomy is "tactile anatomy," but such a book has yet to be written.—I am, etc.,

S. T. PRUEN, M.D.

Cheltenham, March 4th.

ANTIMALARIAL MEASURES.



SIR,—In view of recent correspondence about the advantages or otherwise of screening buildings in malarial countries the following facts may be of interest. Until the year 1925 no attempt had been made to introduce screening of barracks into India. The Indian Government considered it too expensive, and the climate-wise said it was impracticable because it would make the barracks so hot that the inhabitants would die of heat exhaustion. In the Punjab two military stations continued year after year to record a high incidence of malaria in spite of the yearly antimalarial campaign of drainage, oiling, quinine prophylaxis, etc. One station was Miam Mir, renamed Lahore Cantonments to dissociate it from its evil reputation as a pestilential spot. The other station was Amritsar. Both places in 1925 had a very high malarial incidence. In 1926 the infantry barracks at Lahore Cantonments were mosquito-proofed with a 1/16-inch mesh rustproof gauze wire netting, fitted with corridor swing doors, and rendered fool-proof and mosquito-proof. The same thing was done at Amritsar. The soldiers occupying these barracks found them cooler than the non-screened barracks, and blessed the mosquito-proofing, as it did away with the mosquito-bar net for each individual bed cot, its stuffiness, and the time and trouble spent on putting it up, taking it down, and keeping it in repair. Another advantage was that the electric punkah could swing close down over the sleepers, and they derived the full benefit of the current of air. The malarial incidence for Lahore and Amritsar dropped 50 per cent. in 1927 and 1928. I am told the improvement still continues, and I also hear that all new military buildings in malarial districts to be built in India will be screened.—I am, etc.,

COLONEL LATE R.A.M.C.

February 25th.

THE HUNTER FAMILY.

SIR,—In your issue of February 22nd, in a report of the Hunterian Oration by Professor Hey Groves, the following statement is made: "We have also to deplore the loss of the last known descendant of the Hunter family in the person of Miss Helen Hunter-Baillie, the great-grand-niece of John Hunter, who died in February, 1929, at the age of 86." May I point out that this is incorrect? This great lady was the last of her generation—the third generation—but the children of her two married sisters are still alive and are great-great-grand-nieces of John Hunter. These are the children of Mrs. Oliver, of whom four are alive, and the three daughters of Mrs. Maconechy. These are the fourth generation. The four children of Miss Muriel Maconechy, my wife, are the sole representatives of the fifth generation.

The accompanying genealogical tree makes this descent more clear than it can be expressed in writing.—I am, etc.,

Guildford, March 1st. T. B. JOBSON, M.D.

THE RED CROSS CLINIC FOR RHEUMATISM.

SIR,—May I make known through your columns that the Red Cross Society's clinic for the treatment of rheumatism, which H.M. the Queen opened on March 4th, will be available for treatment on and after March 17th, and that applications for appointments may now be made either by letter or telephone. Between now and the opening date representatives of approved and friendly societies, trade unions, and others interested in the treatment of rheumatism are invited to visit the clinic and inspect the building and its equipment.

As the medical press all along has taken so great an interest in the progress of the clinic from the days when it was a scheme on paper only right up to the present time, I am desired by the committee to ask you to give them the opportunity of acknowledging with gratitude the co-operation the British Red Cross Society has received from so many sources in organizing, furnishing, and equipping the clinic. Particularly I would mention the authorities of the spa and of the Royal Mineral Water Hospital at Bath, and of the Devonshire Hospital, Buxton, in the training of our staff, and the very great help accorded to us by the spas and by the medical profession, all of whom regard the clinic as a step, and a big step, towards a wider appreciation among the general public of the value of physiotherapy in the treatment of rheumatic diseases.—I am, etc.,

London, W., March 7th. F. C. DAVIES, Secretary.

Obituary.

MAURICE RICHARD JOSEPH HAYES, F.R.C.S.I.,

Professor of Materia Medica and Therapeutics, University College, Dublin; Consulting Radiologist, National Maternity Hospital, Dublin.

WITH much regret we announce the death of Professor M. R. J. Hayes, F.R.C.S.I., which took place at his home in Monkstown, co. Dublin, on March 2nd.

Maurice Richard Joseph Hayes was the son of Thomas Hayes of Oola, co. Limerick, and was born in 1878. He received his early education from the Jesuits at Mungret College, Dublin, and was an ecclesiastical student for some years. He then entered the Catholic University Medical School, Dublin, and obtained the diplomas L.R.C.S.I., L.R.C.P.I., and L.M. in 1906; two years later he became a Fellow of the Royal College of Surgeons in Ireland. He was also a Fellow of the Royal Academy of Medicine in Ireland. In 1907 he was appointed radiologist to the Mater Misericordiae Hospital, Dublin, but resigned after some time, and entered that private practice which was to become so large in recent years, in consequence of his widespread repute as a radiologist and a recognized authority on deep ray (Erlangen) treatment. In 1917 he received a commission as captain in the Royal Army Medical Corps, and, later, on the establishment of the Free State, he was appointed Major-General, and later Director-General of the Irish Free State Army Medical Corps, rendering great service in the organization of that branch during those troubled years.

As a radiologist his opinion was highly valued, and he made it a practice to keep abreast with the latest advances in that branch of science. He attended congresses and conferences all over Europe, and was a well-known and popular speaker at many of these functions. In 1928 he was appointed by the Minister for Local Government and Public Health to represent the Free State at the International Convention on Cancer in London, and last year he attended the International Congress on Medicine at Cairo. He frequently contributed to debates on his own subject, and wrote many valuable papers to medical journals. He spoke at the last meeting of the Dublin University Biological Society. Throughout his whole medical career he took a very active part in medical politics. During the National Health Insurance fight he acted as medical secretary of the Conjoint and Irish Medical Committees until the appointment of the Irish Medical Secretary of the Association in 1914. He was one of the most active members and supporters of the British Medical Association in Ireland. He was vice-president of the Leinster Branch, 1924–28; president, July, 1928, to April, 1929; member of the Leinster Branch Council, 1918–29; honorary secretary of the Dublin Division, 1914–23; and member of the Dublin Division Executive Committee, 1918–29. He was honorary secretary of the Section of Electro-therapeutics and Radiology at the Annual Meeting of the British Medical Association in Aberdeen in 1914, and vice-president of the Section of Radiology at the Annual Meeting in Edinburgh in 1927. He was elected a direct representative on the Free State Medical Council in August, 1927.

Professor Hayes had been ill for a period of about three or four weeks. At first his ailment appeared to be influenza, but subsequently it took a septic turn and affected his heart. His health had been undermined by his continuous x-ray work, and he himself believed that being so constantly in the atmosphere of x rays his heart must suffer, no matter what precautions were taken. He married in 1926 Agnes, daughter of Mr. Owen Walsh, of Ninch Park, Laytown, co. Meath, who, with two sons and two daughters, survives him.

[The photograph reproduced is by Lafayette, Dublin.]

H. STANSFIELD COLLIER, F.R.C.S.,

Formerly Surgeon to St. Mary's Hospital and the Hospital for Sick Children, Great Ormond Street.

HORACE STANSFIELD COLLIER, who died on February 26th, will be remembered with affection and gratitude by many of his contemporaries at St. Mary's Hospital and at the Hospital for Sick Children, Great Ormond Street. He was a student of St. Mary's Hospital, and before qualifying in 1888 decided upon surgery for his future career. The enthusiasm and energy displayed in his work were remarkable, and it is feared were the cause of his early breakdown in health at a time when he had risen to a high position in the surgical world of this country. He was demonstrator of anatomy at St. Mary's Hospital from 1894 to 1898, and surgical tutor from 1897 to 1902. In 1897 he was elected to the staff of St. Mary's Hospital as assistant surgeon, and shortly after this was appointed to the surgical staff of the Great Ormond Street Hospital. He did a colossal amount of surgery during the period 1897–1911, and completely overtaxed a constitution that was none too strong—his health giving way in 1911, which necessitated his retirement from hospital practice.

Stansfield Collier was a man of most lovable disposition and attractive personality. He gathered round him a host of friends among his colleagues, students, and the practitioners with whom he became associated. His generous disposition always made him thoughtful of the future careers of those junior to him, whether in surgery, medicine, or any of their branches, and he spared no effort to help and encourage them in their early struggles. There are many occupying high positions in the medical profession today whose successful careers were largely due to the helping hand extended to them by Stansfield Collier. His career as a surgeon was meteoric. The brilliancy of his diagnosis and operative skill soon made him known far outside the confines of the hospitals with which he was associated. He speedily acquired a very large practice and was in great demand all over England. He was a man of great originality, both in operative technique and in the scientific after-treatment of his cases. He spared no effort, however desperate the situation might be, and he never gave up hope, so that on many occasions most remarkable recoveries resulted in apparently hopeless cases. One example may be mentioned. A gymnastic instructor in the army fell in the course of his exercises and fractured the sixth and seventh cervical vertebrae. He lay completely paralysed for some months. Collier performed the operation of laminectomy, removing the broken fragments of bone pressing on the cord. This patient made a complete recovery and afterwards became the faithful chauffeur to his surgeon until his retirement from practice.

Stansfield Collier was a brilliant and attractive teacher, and was held in the highest esteem by the large number of students who attended his lectures and tutorial classes in surgery. He wrote many original articles, which appeared in the medical journals.

W. H. WILLCOX.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 8th the following medical degrees were conferred:

M.B., B.CHIR.—C. L. Owen, J. R. S. Webb, C. G. Windsor.
M.B.—G. W. Pickering.
B.CHIR.—C. F. Blockington.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week discussed unemployment, fiscal policy, and various Supplementary Estimates. On March 11th, in committee on the Coal Mines Bill, the Government was defeated by 274 votes to 282. Mr. MacDonald announced that consideration of the bill would continue. No dissolution of Parliament is contemplated.

The Parliamentary Medical Committee met on March 11th, Dr. Salter presiding. It accepted an invitation by the recently formed Scientific Section of Parliament, of which Lord Rayleigh is chairman and Major Church secretary, for a joint meeting to discuss the disposal of refuse and sewage. It also invited the Scientific Section to attend an address on medical science and industry, to be delivered by a spokesman from the London School of Hygiene and Tropical Medicine.

At the same meeting the Parliamentary Medical Committee was addressed by Sir Malcolm Delevingne on control of the narcotic drug traffic by the League of Nations. He reviewed the opium traffic in China, which, with the breakdown of the Government, had much increased, and was encouraged by the military commanders. He also surveyed the traffic in refined derivatives in Europe and America, commenting on the low proportion of addicts in the United Kingdom. He said this country was interpreting the law in its spirit, whereas certain Continental countries followed the letter. The League of Nations was recommending a model administrative code to signatories of the Opium Convention.

Mental Treatment Bill.

COMMITTEE STAGE CONTINUED.

The Mental Treatment Bill was further considered by a Standing Committee of the House of Commons on March 6th. The committee resumed discussion of Clause 2, which provides for the notice of the reception, death, or departure of voluntary boarders, and makes provisions as to boarders who become incapable of volition. On the motion of Mr. ARTHUR GREENWOOD Subsection 3 was amended so as to substitute another form of words for "incapable of volition." The Minister said that when his amendment was made the subsection would read:

"If any person received as aforesaid becomes at any time incapable of expressing himself as willing or unwilling to continue to receive treatment, he shall not thereafter be retained as a voluntary patient for a longer period than one month, and shall, if he has not been previously discharged, be discharged on the expiration of twenty-eight days from the date on which he became incapable of so expressing himself, unless in the meantime he has again become capable of so expressing himself or steps have been taken to deal with him either under the principal Act as a person of unsound mind or under Section 5 of this Act as a person who is likely to benefit by temporary treatment."

The Minister said the new words "expressing himself as willing or unwilling to continue to receive treatment" had been carefully considered in the light both of the medical and of the legal issues involved, and the term "incapable of volition" would disappear from the bill entirely. Certain other amendments would have to be made in later clauses of the bill.

Sir BOYD MERRIMAN withdrew the amendment he had moved at the previous sitting to cover the same point, and the committee agreed to Mr. Greenwood's amendment, although Mr. Charles Williams added a warning that it might have to be reconsidered on report.

Dr. FREMANTLE moved to amend Subsection 3 further by substituting "six months" for "one month" as the period during which a voluntary patient might be retained after becoming incapable of expressing willingness to continue treatment. He said medical experience did not hesitate to say that one month was not long enough to give the patient in which to change his condition without having to be certified or discharged. This was the definite experience of the medical superintendents and of the London County Council. In its Maudsley Hospital that Council had unique experience in treating cases which were medically described as "ins and outs." These cases were very common, and under suitable conditions, such as those at Maudsley Hospital, they recovered, but very seldom did so within a month. When a patient was very melancholic and submitted to voluntary treatment, but after a short time lost volition, such a patient required three months or more to recover, and the general experience of Maudsley Hospital was that six months was required. Parliament wished to prevent the certifying as a lunatic of a woman who had an attack of mental disorder during confinement or afterwards, and who, coming in as a voluntary boarder, lost volition but recovered it after three months. Under the bill as it stood she would be treated under the Lunacy Act.

Mr. GREENWOOD said the committee must remember that it was dealing with people who of their own free will went into an institution as voluntary patients. It would be very serious to

suggest that if a person who thought he was going in for a fortnight or three weeks lost control of himself he should be incarcerated for six months.

Dr. FREMANTLE protested against the word "incarcerated." He said the committee was endeavouring to get these patients treated with the best hospital treatment.

Mr. GREENWOOD said that the detention of a person for a long period of time, if not anticipated when that person went in as a voluntary boarder, was next door to incarceration. He denied Dr. Fremantle's suggestion that at the end of a month the patient who had lost volition would immediately be certified as a lunatic. The voluntary boarder would be transferred to the category of persons who could not look after themselves, but who could recover under treatment, and for whom, under Clause 5, treatment would be available without certification.

Mr. HASTINGS said that patients who, after being admitted voluntarily to hospital became definitely, though temporarily, insane, but were clearly able to express themselves as unwilling to receive treatment, could not come under Clause 5. As the bill stood, with the new wording which the Minister had put into it, temporarily insane patients who desired to get out would have to be certified after a month.

Sir BOYD MERRIMAN said that a refractory patient who refused voluntarily to submit to treatment was entitled, under Clause 1, to walk out of the hospital unless steps were taken to keep him there. If he was incapable of expressing willingness or unwillingness he could be dealt with under Clause 5, but if he definitely refused he must be certified. He agreed with the Minister that, to avoid raising the question of the liberty of the subject, the period must be one month and not six months.

Dr. FREMANTLE asked if the Minister's interpretation of the bill was that when a person became incapable of looking after himself he could be kept one month as a voluntary boarder even though he had lost volition, and could then be treated under Clause 5 as a temporary patient for another six months. Did the Minister mean that the patient, having lost volition, would be allowed seven months before he was finally certified?

Mr. GREENWOOD: And possibly a period of a second six months after that.

Dr. FREMANTLE then withdrew his amendment, and moved as an alternative:

"Or (if received at an institution or hospital for voluntary boarders only) for a longer period than six months."

He said this was the next best proposal advanced by the London County Council as the result of experience in the Maudsley Hospital, which was run on the highest plane of medical therapeutics.

Mr. GREENWOOD could not accept the amendment, as he saw no reason for giving special institutions power to detain persons for another six months.

The amendment was then negatived, and further drafting amendments were made to carry out the intention of the Minister in Subsection 3, Clause 2.

Dr. FREMANTLE moved to add at the end of Subsection 3 the words:

"Provided that any written declaration by him, if he is over 16 years of age when he was capable of volition, desiring that in the event of his losing volition his status should for a period of six months remain unaltered, be legal and binding on all concerned."

He said he was trying to state the case for those with most experience—the Royal Medico-Psychological Association.

Mr. GREENWOOD said that while this amendment might appeal to many medical men it was very serious to propose that a person should sign away his liberty beforehand. When the stage arrived at which the patient was incapable of looking after himself the question should be taken on its merits without any previous undertaking having been given. In any event, such a new method of dealing with a voluntary patient would need more consideration than could be given it in a small amendment.

Dr. FREMANTLE said the interests of those who had asked him to move the amendment were to get the bill through. He agreed that the amendment proposed was a big one, and he hoped it would be raised some years hence in an amending bill. In the meantime he withdrew it.

Clause 2, Subsection 4, deals with the case of a patient under 16 who ceases to have any parent or guardian, or whose parents or guardians do not perform their duty towards him. The subsection provides that the person in charge shall report the circumstances of the case to the Board of Control, which shall give such directions as it thinks fit. Dr. VERNON DAVIES moved to add words to make this section operative in cases where the parents or guardians "fail to remove such person from the institution, hospital, home, or place when so requested in writing by the person in charge."

Mr. GREENWOOD said the object of the amendment was covered by the word "duty," but if the proposed words were inserted it would seem to be the main duty of a guardian to take his ward away from an institution when it was convenient for the person in charge rather than when it was for the real convenience of the patient.

Dr. VERNON DAVIES withdrew his amendment.

Mr. KINLEY moved in the same subsection to provide that the Board of Control should take action "in conjunction with the local authority for the area."

Mr. GREENWOOD said the Board of Control was an independent safeguard of persons who were in these institutions. If the Board was compelled to act in agreement with local authorities that would immediately destroy one of its important functions. If it differed from the local authority there would be no machinery for settling what was to happen to the patient.

Dr. FREMANTLE said the Board of Control would wish to be in touch with the local authorities and to use their machinery.

Mr. GREENWOOD said the Board already possessed such powers as were needed, and it was not necessary to give them any more.

The amendment was then negatived.

Clause 2, Subsection 5, runs:

"If any person fails to give any notice required to be given by him under this section he shall for each day or part of a day during which the default continues be liable to a penalty not exceeding five pounds."

Mr. KINLEY moved to omit the subsection. He said the committee had agreed on a previous amendment that the limitation of damages was a wrong principle.

Mr. GREENWOOD said that in the previous case the committee had been dealing with damages to persons wrongfully detained. This subsection did not deal with the same kind of offence. It proposed a fine because people were not doing their duty, and if the words were cut out nobody could be punished. He doubted whether, in a case where the Board of Control had not been notified, they would ever be able to recover damages.

Sir BOYD MERRIMAN said there might in common law be an obligation to give notice of death to the Registrar of Births and Deaths, and also, in certain cases, to the coroner, but he did not think there would be, without a penalty, power to enforce notification to the Board of the reception of a patient or of his death. It would be difficult for the Board of Control to prove as an ordinary litigant that it had suffered any damage from non-receipt of such a notice.

Mr. GREENWOOD said penalties were provided under the Lunacy Act for similar failures to carry out duties, but not for this particular case.

Dr. FREMANTLE asked why the imposition of penalties could not be left to the local authorities. They were trusted with minor matters, and it seemed retrogressive to put a penalty in the bill. In some cases the local authority might not consider it necessary to inflict a definite penalty, but would get its way by other means.

Mr. GREENWOOD said the clause did not deal merely with local authorities. Some of the institutions were not under their control. Considering the number of private institutions it was clear that Parliament ought to have some safeguard in the form of a penalty which would keep people up to their responsibilities.

The committee then agreed to Subsection 5 with a drafting amendment to make clear that the obligation to give notice referred to events both under Subsection 1 and Subsection 2.

Clause 3 deals with the visitation of voluntary patients, and provides that any Commissioner may at any time visit such a patient and report to the Board of Control on the case, which may at its discretion order the discharge of the patient, or his treatment as a person of unsound mind under the Lunacy Act, or else as a person incapable of volition and under the present bill.

Mr. RICHARD RUSSELL moved an amendment to provide that any visit by a Commissioner should only be "at the request of any person received as a voluntary patient or under the provisions of any local Act."

Mr. GREENWOOD said the idea that the Board of Control ran about certifying people was without any foundation. For the general protection of persons under the bill it was essential to keep independent power of inspection by the Board.

Admiral BEAMISH thought that it ought to be possible to combine the clause and the amendment so that a Commissioner might at any time visit a patient, and any voluntary patient might request a Commissioner to come and see him. He asked whether the bill permitted the voluntary patient to get in touch with the Commissioners.

Mr. GREENWOOD said that at present any resident in an institution, or his friends or relatives could make representations to the Board of Control, and it was to-day one of the normal functions of the Board to carry out regular systematic inspection of these places. But if every voluntary boarder could demand the presence of a member of the Board of Control there would be an enormous increase in the bureaucracy. They could not give the right to every individual that he should be visited by the Board. The work would be utterly beyond the power of any Board of practicable size.

Sir BOYD MERRIMAN asked whether the clause contained any real safeguard. If there were to be only five Commissioners was there any real probability that these would visit voluntary patients with sufficient frequency to make their visits of real effect?

Mr. GREENWOOD said there were to be five members of the Board, but it was also proposed to have a considerable staff of visiting Commissioners in addition. While the Board of Control would keep in touch by visitation, its primary work would be central administration.

Dr. FREMANTLE said it was true that Clause 11 provided for Commissioners other than the Board of Control. Those who were now being turned off the Board of Control would be free and available to go on visits, but the bill proposed that on their deaths they should only be replaced by assistant commissioners and inspectors. An amendment was needed to Clause 11 to provide that the senior Commissioners not in the Board of Control should be continued in their proper status to carry out the duties of visitation under Clause 3.

Mr. Russell's amendment was then negatived.

Mr. KINLEY moved another amendment to provide that any order by the Board of Control changing the status of a voluntary patient should only be made with the approval of the local authority for the area. He said that the local authority would be a safeguard against the bureaucracy which was centred in London, and would secure that a patient was not spirited away without his medical man or the local medical officer of health having power to say a word in his defence.

Mr. GREENWOOD said the question to be decided was a patient's mental state and whether he was fit to be treated as a voluntary patient. That was an expert question on which the Board of Control, with all the information on the case at its disposal, ought to be capable of making a decision. The last safeguard must be the law courts.

Mr. Kinley's amendment was defeated. Clause 3 was added to the bill, and the committee adjourned until March 11th.

Clause 4 was discussed on March 11th.

Miss LAWRENCE resisted an amendment, moved by Dr. Vernon Davies, to extend to other institutions and to the domiciles of single cases the permission to receive and lodge friends or relatives of voluntary patients, which the clause accords in registered hospitals and licensed houses. Miss Lawrence said the permission was already possessed by licensed houses. Registered hospitals which were not supported by public funds desired the same concession. Public authorities did not, lest half their time should be taken up by refusing applications.

The amendment moved by Dr. Davies was rejected.

Dr. FREMANTLE moved an amendment to provide that, in calculating the number of inmates of a licensed house, relatives should not be reckoned if not occupying accommodation approved by the Board of Control. He did so on behalf of several associations representing those who controlled such houses.

Miss LAWRENCE said the Board had to be strict in such matters. Additional visitors might be accommodated in a villa. The Government wished to leave the licensed houses in cold storage so far as this bill was concerned.

Dr. MORRIS-JONES pointed out that licensed houses were not allowed to increase their beds beyond those authorized in 1890. Consequently the permission to admit relatives would only be used in exceptional cases.

Mr. GREENWOOD contended that if a visitor occupied accommodation not licensed by the Board of Control no question would arise. He was prepared to consider the point of substance, if any, on the report stage.

Dr. FREMANTLE withdrew his amendment and the committee agreed to Clause 4 with drafting amendments.

Clause 5 provides for treatment without certification of persons temporarily incapable of expressing themselves as willing or unwilling to receive such treatment.

Sir BASIL PETO moved that admission to an institution maintained by a local authority should not be to an asylum, mental hospital, registered hospital, or licensed house. This would assure patients that they were not to be spirited away to an asylum and put on the road leading to permanent detention.

Mr. GREENWOOD said between a quarter and a third of the persons now in mental hospitals would, when the bill passed, be treated as temporary patients. Local authorities would not accept the burden of providing new accommodation for them.

Mr. WOMERSLEY said the Association of Municipal Corporations was already of opinion that substantial financial assistance would be required to carry out their obligations under the bill.

Mr. SOMERVILLE HASTINGS suggested that temporary patients would be better treated in the municipal hospitals which would be taken over on April 1st. The Middlesex Hospital received numbers of such patients. It found that many suffered from some physical condition, which required to be treated in a general hospital. To treat these temporary patients in an asylum might have a deleterious effect.

Sir BASIL PETO pressed his amendment. The mere fact of taking people to the vast institutions called mental hospitals was sufficient in most cases to ensure keeping them there for ever.

Mr. GREENWOOD cited the report of a large mental hospital two-thirds of whose admissions were voluntary. He could not agree to divert to mental cases beds in general hospitals, which were needed for general cases, while special provision was available in institutions provided for mental cases. Nor could he agree to separate the medical men treating early cases from other specialists in mental disease. Local authorities already had powers to deal with early cases in special institutions, but to command them to do so would put upon them an impossible burden and bring the bill to nought.

The amendment was defeated and the committee adjourned.

Tuberculin-tested Cows and Cattle Shows.

Mr. GREENWOOD, in a reply to Mr. Christie on February 27th, said he had informed producers of certified and Grade A (T.T.) milk that he could not in future consent to the temporary withdrawal of animals from licensed herds for the purpose of sending them to a show unless the show was restricted to tuberculin-tested cattle. Conditions at shows where both tested and untested animals were housed involved serious risk of infection to the tested animals. He had consulted the Minister of Agriculture before coming to this decision.

At the House of Commons on March 4th, the Conservative Agricultural Committee decided to make representations to the Ministry of Agriculture against this decision. Miss LAWRENCE told Dr. Vernon Davies, on March 5th, that it was possible, by exercising sufficient care, to obtain clean milk from cows living in defective cowsheds, but there was more difficulty in producing clean milk in unsatisfactory surroundings, and for practical purposes the structural conditions laid down in the Milk and Dairies Order were the minimum that should be required as a basis for the production of clean milk. In answer to a further question by Dr. Davies, Miss Lawrence said that the only satisfactory test for tubercle bacilli in milk was one which took several weeks to carry out, and it was therefore necessary, in order to obtain the maximum possible safeguard, to lay down conditions as to the testing of the cattle and their isolation from untested animals. When a cow was found to be tuberculous it was rarely possible to determine how she had become infected, but the association of tested with untested animals at a show involved a risk of infection unjustifiable in the interests of consumers.

Housing Conditions.

The Bishop of Southwark, in the House of Lords on February 26th, called attention to recent annual reports of medical officers of health on bad housing conditions, and asked the Government when it proposed to introduce legislation dealing with the slums.

Lord MARLEY, replying for the Government, said that the reports which the Bishop of Southwark had cited were seriously disturbing the Government. Ministers felt that these reports understated the actual position. The debate was adjourned to March 4th.

On March 4th the House of Lords resumed the debate. Lord DICKINSON said that the Royal Commission of 1885 pointed out that nearly 900,000 people were living in London in an overcrowded condition; after forty years' continuous labour on the part of local authorities, there were still 800,000 people living in London under these conditions.

Lord PARMOOR said the Government intended to introduce a slum clearance bill this session and pass it into law. There would be nothing in the bill to discourage reconditioning, but that would not be one of its main features. The Association of Municipal Corporations considered that any large measure of reconditioning would hinder the carrying out of slum clearance schemes. The Government considered that the work of providing alternative dwellings while slum clearance schemes were being carried out was absolutely necessary, and they intended to press on as quickly as possible with such schemes. They also contemplated that local authorities should undertake in advance larger amounts of new building. He hoped that the Government would have the honour of introducing a really drastic measure in order that the abomination of the slums should be ended.

Therapeutic Value of Vitamin Extracts.—Dr. FORGAN, on February 27th, asked Mr. Greenwood if he would institute an inquiry into the therapeutic and prophylactic values of medicinal and nutritional preparations of vitamin extracts, with a view to their standardization and prescription, as far as deemed advisable, under the National Health Insurance scheme. Mr. GREENWOOD replied that methods for the quantitative estimation of vitamins were being actively studied under the auspices of the Medical Research Council. Knowledge in the subject was not yet sufficiently advanced to justify the consideration of the question of adopting and applying official standards of strength for medicinal preparations of these substances.

Vaccination of Workhouse Inmates.—Dealing, on March 6th, with an allegation by Mr. Carter that 400 pauper inmates of St. Pancras Workhouse were vaccinated without their consent being asked, Mr. GREENWOOD said an inmate had had small-pox for three or four days, and it was considered advisable medically to examine the other men, and to advise them to be vaccinated. Any who objected were at liberty to refuse. No leave was stopped on this account. One man had stated that he had been told, on arriving with a new admission order, to be vaccinated or get out. Mr. Greenwood explained that the delay in readmitting this man was due to a misunderstanding not likely to recur. The duty of a Poor Law authority would not be affected by a refusal of the applicant to be vaccinated, but in certain circumstances it might be proper that relief should not be given in a particular institution.

Eyesight Tests for Motor Drivers.—During consideration of the Road Traffic Bill by a Standing Committee of the House of Commons, on March 11th, Dr. SALTER moved an amendment to require an applicant for a driving licence to produce a certificate stating that he had satisfactorily passed an eyesight test as to visibility and colour. The amendment was rejected by 11 votes to 4, after Dr. Salter and others had discussed night-blindness and colour-blindness in drivers.

Medical News.

AT a meeting on February 7th of prominent citizens of Winnipeg, including medical practitioners and their wives, a congratulatory address was presented to Dr. W. Harvey Smith, president-elect of the British Medical Association and of the Canadian Medical Association. The address, which was tendered on behalf of the Winnipeg Medical Society, referred in laudatory terms to the services rendered in the past by the president-elect, and gratitude was expressed for the assistance and the sympathy given by Mrs. Harvey Smith.

THE William Mackenzie medal for 1929 for original contributions to ophthalmology of outstanding merit has been awarded by the custodians, the Glasgow Eye Infirmary, on the advice of a committee representative of the University of Glasgow, the surgeons of the Glasgow Eye Infirmary, the surgeons of the Glasgow Ophthalmic Institution, and the Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow, to Professor Dr. van der Hoeve of Leyden, Holland.

THE Section of Anæsthetics of the Royal Society of Medicine will hold a reception at the Wellcome Historical Medical Museum, Wellbeck Street, W.1, on Wednesday, April 2nd, at 8.30 p.m. During the evening Lord Dawson of Penn, president of the society, will give an address on Henry Hill Hickman. As announced in the letter from Dr. Cecil Hughes, honorary secretary of the Hickman Memorial Fund, published in our issue of February 22nd, the memorabilia connected with Hickman which have been collected by Mr. Henry Wellcome will be on view.

THE Minister of Health will open the department for treatment of cancer by radium at the North Middlesex Hospital, Edmonton, on the afternoon of Tuesday, March 18th. Mr. Greenwood will also lay the foundation stone of the extension to the nurses' home which has been provided by the Edmonton Board of Guardians.

AT the meeting of the Medico-Legal Society, at 11, Chandos Street, W.1, on Thursday, March 27th, at 8.30 p.m., Professor J. S. Haldane will read a paper on carbon monoxide poisoning and its medico-legal aspects; a discussion will follow.

AN extraordinary general meeting of the Cremation Society of England will be held at 23, Nottingham Place, W.1, on Wednesday, April 2nd, at 3 p.m., to consider and if approved pass a special resolution changing the name of the company to "The Cremation Society." The annual meeting of subscribers will be held immediately after the extraordinary general meeting, when the report and financial statement for 1929 will be submitted.

THE next meeting of the London Clinical Society will be held at the London Temperance Hospital on Tuesday, March 18th. It will be a clinical evening. Cases will be on view from 8.30 p.m.

THE Irish Medical Schools' and Graduates' Association will hold a dinner on St. Patrick's Day, March 17th, at 7.45 p.m., at the Savoy Hotel, London (Abraham Lincoln Room). The guest of honour will be Mr. Cecil B. Harmsworth.

AT the meeting of the Royal Microscopical Society to be held at 20, Hanover Square, W.1, on Wednesday, March 19th, at 7.30 for 8 p.m., Mr. Joseph E. Barnard, F.R.S., will deliver his postponed presidential address on resolution and visibility in medical microscopy.

A MEETING of the West Kent Medico-Chirurgical Society will be held at the Miller General Hospital, Greenwich, S.E.10, to-day (Friday, March 14th), at 8.45 p.m. Dr. H. V. Morlock will read a paper on the treatment of heart failure.

THE Fellowship of Medicine announces that Dr. John Parkinson will lecture on *x*-ray examination of the heart on Tuesday, March 18th, at 4 p.m., at the Medical Society, 11, Chandos Street, Cavendish Square. There will be two clinical demonstrations on Thursday, March 20th: one at 2.30 p.m., at the Royal Westminster Ophthalmic Hospital, Broad Street, W.C., by Mr. M. L. Hine, and the other at 3 p.m., at the National Hospital for Diseases of the Heart, by Dr. F. W. Price. The lecture and demonstrations are free to medical practitioners. Two special courses begin on March 17th: one in neurology at the West End Hospital for Nervous Diseases, Welbeck Street, will take place daily at 5 p.m. for a month, and the other on venereal disease at the London Lock Hospital, occupying every afternoon and evening for four weeks. From March 24th to April 12th there will be an all-day course in medicine, surgery, and gynæcology at the Royal Waterloo Hospital; and from March 31st to April 5th an all-day course in gastro-enterology at the Prince of Wales's Hospital, Tottenham. Copies of all syllabuses and information in regard to post-graduate work in London, including details of the general course, consisting of attendance at the clinical practice of more than forty London hospitals, may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

AT a reception held at the Egyptian Legation in London on March 12th the Chargé d'Affaires, Dr. Hamed Mahmud, presented to Lord Moynihan of Leeds, President of the Royal College of Surgeons, the Grand Cordon of the Order of the Nile, bestowed on him by His Majesty King Fuad.

THE KING has appointed Dr. Norman Scott Carmichael to be Surgeon-Apothecary to His Majesty's Household at the Palace of Holyroodhouse, in succession to Dr. William Macrae Taylor, deceased.

DR. J. MURDOCH, chief medical officer of the department of radiology and radium therapy at the Burgmann Hospital, Brussels, will give an address at the University of Sheffield on Tuesday, May 6th. This will be the third of a series arranged by the University in co-operation with the Yorkshire Branch of the British Empire Cancer Campaign. Dr. Murdoch has charge of the Service des Tumeurs at the Burgmann Hospital, and his address will be devoted to the subject of radium therapy in cancer. The address will be open to all medical practitioners. Details as to time and place will be announced later. In order to facilitate arrangements practitioners from outside areas wishing to attend are asked to send their names to the secretary, Clinical Studies Committee, The University, Sheffield.

WE have received from Dr. Kumud Sankar Ray, joint honorary secretary of the Indian Medical Association (formerly the All-India Medical Association), 6A, Corporation Street, Calcutta, four printed documents relating to medical questions now under consideration by the Government of India, with special reference to the future of the independent medical profession in that country: (1) Resolutions passed at the sixth session of the All-India Medical Conference, held at Lahore on December 27th and 28th, 1929; (2) Dr. B. C. Roy's presidential address to the conference; (3) an address by Colonel B. Nauth, I.M.S. (ret.), chairman of the reception committee; and (4) "Some problems of the medical profession in India," compiled for the Association by Dr. K. S. Ray. These publications may be consulted in the library of the British Medical Association, Tavistock Square, London.

WE are asked to state that hospitals situated within eleven miles of St. Paul's desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1930 must make application before March 31st to the honorary secretaries of the Fund at 7, Walbrook, E.C.4 (G.P.O., Box 465A). Applications will also be considered from convalescent homes which are situated within the above area, or which, being situated outside, take a large proportion of patients from London.

AN article by Sir Thomas Oliver on pulmonary asbestosis appeared in the *Archiv für Gewerbepathologie und Gewerbehygiene*, 1930, Band I, Heft 1 and 2. Reference is made to the publication in the *Journal* of December 3rd, 1927, of the papers by Sir Thomas Oliver, Dr. W. E. Cooke, and Professor Stuart Macdonald, which were read at the Annual Meeting in Edinburgh that year, and certain new cases are now described.

IN a circular letter addressed to local authorities the Minister of Health states that as the rate of Civil Service bonus now payable on the basis of an average cost of living figure of 70 will remain in operation for six months commencing March 1st, there will be no alteration during that period in the range within which bonus may be paid by local authorities to those of their officers whose remuneration is subject to the Minister's sanction.

WE are informed by the Ministry of Health that the Pan-Hellenic Health Exhibition, announced in our issue of February 15th, p. 319, has had to be postponed indefinitely owing to the impossibility of finding suitable premises.

A SCHEME has been issued by the Ministry of Health under section 101 (6) of the Local Government Act, 1929, setting forth the annual contributions to be paid from April 1st, 1930, to March 31st, 1933, by the London County Council and by the councils of the metropolitan boroughs to voluntary associations providing maternity and child welfare services in the County of London. Councils are authorized to require the observance of conditions relating to the efficiency, alteration, inspection, and financial supervision of the service provided, but the consent of the Minister of Health must be obtained before any contribution may be reduced or terminated. Disputes and differences arising between councils and voluntary associations are required to be referred to the Minister, whose decision is final and binding.

THE March issue of *The Prescriber* is largely devoted to spa treatment, emphasis being laid on the merits of British spas and mineral waters. Articles are contributed by Drs. Fortescue Fox, H. E. Rhodes, J. R. Collins, G. V. Worthington, and F. A. Mearu.

THE Paul Ehrlich gold medal for 1930 has been awarded to Professor Karl Landsteiner of Vienna by the Rockefeller Institute of New York for his discovery of human blood groups.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh)

QUERIES AND ANSWERS.

INFANTILE SEBORRHOEIC ECZEMA.

"M.B., CH.B." writes: I would be grateful for suggestions in the treatment of the intractable infantile seborrhoeic eczema sometimes found in otherwise healthy breast-fed babies. A baby, breast-fed nine months, has had it, more or less, since 5 weeks old; eight teeth; irritation intense.

HYPERIDROSIS AFTER HYSTERECTOMY.

"E. G." writes: A patient who had a panhysterectomy performed three months ago is suffering from almost continuous attacks of sweating. I have tried all the usual remedies, and would be grateful for any suggestions for treatment of this troublesome condition.

PRECIPITATE EJACULATION.

"B.M./J.D.L." writes: The "layman" treatment for this condition is a pint of draught ale half an hour before the act, and I have prescribed it several times with invariable success.

TINNITUS AURIUM.

DR. A. BETTS TAPLIN (Liverpool) writes in reply to Dr. W. A. M. Swan (March 8th, p. 477): I have treated a number of cases of tinnitus aurium of this kind purely by suggestion with marked success, and I recommend him to try this method in the case he mentions.

TURBINATE CAUTERIZATION FOR COLDS.

DR. C. DE W. GIBB (Torquay) writes: In reply to "Relieved" (March 1st, p. 428), I recommend a thorough investigation of the condition of the nasal accessory sinuses as being likely to indicate a treatment capable of eradicating the need of periodic cauterization of the turbinates. I have so often found chronic infection of one or more nasal sinuses in patients previously accustomed to cauterization of the turbinates.

PAIN FOLLOWING HERPES ZOSTER.

DR. CLAUDE WILSON (Tunbridge Wells), *in reply to Dr. Norman Wilson's inquiry (March 1st, p. 427) writes*: About two years ago I found, above the signature of Dr. F. Gardiner (Edinburgh), the paragraph quoted below (Latham and Crisp English's *System of Treatment* (1912), vol. iii, p. 1043). It has been of great help to me and to many of my patients, and is, I think, not widely known. "For the subsequent pain, which is most severe in elderly people, the use of analgesics, such as phenacetin, is often required, but sometimes it is only removed by injections of morphine. Much better, in my estimation, than these drugs is the use of the ethyl chloride spray. Various areas of the skin over the root ganglia and the cutaneous branches may be frozen by this plan on successive days with relief to the patient."

LEAD URINALYSIS.

DR. N. ASHERSON (London, W.1) writes: Your correspondent, "M. D." (*Journal*, March 1st, p. 428) will find that there is only one absolutely delicate test for the presence of minute traces of lead in any tissue or fluid, and that test is the spectroscopic one. Some years ago, in connexion with the lead treatment for malignant disease, I had the opportunity of putting this method to the test. A one-hundredth part of a milligram of lead can be thus detected. Broadly speaking, the test consists of: (1) a photograph of the spectrum of an arc is taken (control spectrum); (2) the tissue or fluid to be tested must be evaporated, dried, or incinerated (not necessarily completely). Urine must be evaporated down and the residue well dried and charred in a receptacle not lead glazed. A portion of the suspected tissue is put in the arc and another spectrum photograph taken. (3) A portion of a salt of the metal whose presence is suspected—for example, lead—is placed in the arc and a third spectrum photograph obtained (known spectrum). Thus, as the three spectra are taken on one plate, and one below the other, a graphic record is obtained and the presence or absence of the similar lines in the spectrum of (2) and (3) will provide the test. The method is a very rapid one, and a whole series of tests can be rapidly determined. Chemists can also, by the spectroscopic test, give a shrewd guess as to the amount of lead present. By this method I was able on several occasions to detect the presence of lead in the faeces of mechanics working with "lead petrol." I would suggest that "M. D." gets in touch with a chemist who is working with spectro-analysis. Any chemistry department of a big college would have the apparatus. I am not surprised that "M. D." found no lead in the urine. In a case of a man, aged 60, who died after eighteen hours as a result of the intravenous injection of 20 c.cm. of "choriotrope" (0.5 per cent. lead), though the urine was blood-stained, the spectroscope showed no trace of lead. There was no trace in the kidney or salivary glands, and only a trace of lead (spectroscopically) in the liver. One can only surmise that the lead had gone to the bones. I radiographed a series of gall-bladders after intravenous lead injection, but the results were negative. Colloidal lead is *not* opaque to *x* rays. I was unable by *x*-ray examinations to detect the deposit of lead in bones.

DR. W. E. COOKE (Wigan) writes in reply to "M. D.'s" question in the *Journal* of March 1st: Lead was found in considerable amounts in the urines of all the cases of lead poisoning from tap water coming under notice. I have no experience of the clinical test mentioned in "M. D.'s" query.

INCOME TAX.

Deductible Expenses.

"E. C. B." finds the income tax on his share in a partnership to be "very high," and desires information as to the basis of return and expenses deductible.

*** The strictly correct basis of stating the gross receipts of a practice is the amount of the gross bookings less a carefully—that is, item by item—calculated allowance for probable losses by bad debts. The Revenue authorities will normally accept the basis of cash receipts, provided that the work of the practice is not expanding and that such receipts include payments received for all practice work, even though handed over wholly or in part to a previous proprietor or partner. This is a practical difference between professional and trade profits which is mutually convenient, but no such difference is provided for by law. The only classes of allowable expense that occurs to us, in addition to those specified by "E. C. B.," are maintenance and repair of instruments, drugs if borne by him, cost of repair and decoration of waiting room and surgery, and depreciation of car.

LETTERS, NOTES, ETC.

BORROWED RADIUM.

DR. ARTHUR WHITFIELD (London, W.) writes: Some two to three years ago I lent my small amount of radium to a doctor to treat a patient of his. Unfortunately I forgot to make a note of his name, and I have no means of finding it. He has probably finished with it and forgotten to return it. If this letter should catch his eye will he kindly send it back to me?

EXHAUST GASES IN THE GARAGE.

As the danger of carbon monoxide in exhaust gases is not fully recognized by all motor car users, the Automobile Association has issued to garages holding the A.A. appointment a showcard giving hints for motorists when running their engines in a confined space. The advice includes the following maxims: "Never run an engine in this garage for longer than is absolutely necessary. Never run the engine for warming or tuning-up unless doors, windows, and other ventilators of the garage are open. Warm up the engine or tune it up in the open air rather than in the garage. Maintain the exhaust system in good condition and free from leakage." Copies can be obtained by members of the A.A. for use in their own garages on application to the secretary, Fanum House, New Coventry Street, W.1.

AN *X*-RAY REPORT BOOK.

MESSRS. H. K. LEWIS AND CO., LTD., medical publishers, 28, Gower Place, W.C.1, have prepared a report book for entering details about patients investigated by *x* rays, with columns for notes about the size and number of the films taken, the part of the body exposed to *x* rays, and a report of the conditions found. The size of the page is 13½ in. by 14 in., and the book is half bound in red sheepskin with cloth sides. The price ranges from £1 7s. 6d. for 50 openings to £1 17s. 6d. for 200.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 52, 53, 54, 55, 58, 59, 60, and 61 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 56 and 57.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 87.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

255. The Etiology of Influenza.

I. S. FALK, R. W. HARRISON, R. A. MCKINNEY, and G. W. STUPPY (*Journ. Amer. Med. Assoc.*, December 28th, 1929, p. 2030) present a summarized preliminary report of a series of studies on the etiology of influenza, which were commenced in Chicago during the height of the epidemic of 1928-29. Experiments were made on monkeys both with cultures of Pfeiffer's bacilli and of pleomorphic streptococci that had been isolated from the blood of a very early human case. Infection with the latter by means of nose and throat sprays and intratracheal injections produced in the animals a disease closely resembling human influenza. Serological studies on samples of blood collected shortly after the epidemic from approximately fifty persons demonstrated the presence, in apparently significant concentrations, of agglutinins against the pleomorphic streptococci and more or less closely related diplococci. The agglutinins were specific so far as this could be determined by absorption tests. Of the many hundreds of cultures isolated from human and monkey sources eight morphological and cultural groups of organisms were definable; of these, however, only two seemed likely to be of etiological significance as regards the epidemic. One group consisted of highly pleomorphic, green-producing streptococci, which varied in their Gram-staining and fermentative properties, and which had not been found normally in the blood or respiratory tract of monkeys. The second group consisted of non-pleomorphic, Gram-positive, relatively large, green-producing diplococci. The organisms of both groups were facultative aerobes, and insoluble in bile. The first group were said to be decidedly more effective in producing experimental influenza in the monkeys. In a significant number of cases infection with these streptococci caused acute disease of the upper respiratory tract in members of the laboratory staff. The investigators deem it not improbable that the pleomorphic streptococci were etiologically related to the influenza outbreak.

256. Psittacosis.

MEYER (*Med. Welt*, January 25th, 1930, p. 117) enumerates several symptoms which he regards as pathognomonic of psittacosis; constant intense thirst is a prominent feature, while severe symptoms of collapse occur early and can be relieved only by the strongest cardiac tonics. Psittacosis produces a peculiar form of pneumonia quite distinct from the influenzal type; tracheitis and bronchitis do not occur, but severe pharyngeal ulceration is common. The physical signs of psittacosis pneumonia resemble those of broncho-pneumonia; dullness is absent, but auscultatory signs are definite. The cerebral symptoms resemble those of typhus fever, there being confusional states, insomnia, and delirium. Bulbar symptoms may supervene in the form of severe tremors, and there is persistent hyperpyrexia with tachycardia. The spleen is always enlarged and diarrhœa very common; the diazo-reaction in the urine is always positive. Leucocytosis and eosinophilia have not been observed. The actual infective agent in human psittacosis is still uncertain, but "Nocard's bacillus," which resembles that of typhus, can be found in human subjects. In some cases, however, a haemolytic streptococcus has been recovered, but its etiological relationship is doubtful, and Meyer believes that some other virus is concerned. Therapeutic treatment is mainly symptomatic, and is especially directed to the cardiac weakness. Blood transfusion has proved efficacious.

257. G. ADAMY (*Deut. med. Woch.*, February 7th, 1930, p. 217) states that Professor Emden and himself discovered several small house epidemics of psittacosis last Christmas at Hamburg, which is the chief port for the introduction of parrots into Germany, into which about 500 parrots are imported monthly. They subsequently learnt that Professor Hegler of St. George's Hospital, Hamburg, had reported three cases in the previous July. Since then the number of cases in Greater Hamburg has risen to thirty, and six have proved fatal. The present author's observations confirm the view that psittacosis is an infectious disease, that inter-human transmission may occur, and that the disease runs a mild course in children and young persons. As a rule it lasts for two and a half to three weeks. The obvious official measures to be taken are supervision, or, better still, complete prohibition, of the importation of parrots.

258. Paroxysmal Tachycardia of Unusual Duration.

L. GALLAVARDIN, P. VEIL, and R. FROMENT (*Lyon Méd.*, January 5th, 1930, p. 3) remark that attacks of paroxysmal tachycardia usually continue for several minutes or hours. While paroxysms of one, two, or even six days' duration are occasionally observed, those lasting more than ten days are extremely rare. Of 160 patients with this disease only eleven had attacks of longer than ten days, and this proportion is certainly high, since the milder degrees of such tachycardia may not come under notice at a clinic. These eleven patients were separated into two groups. In the first group of seven patients the duration of the tachycardia was between ten days and one month, and only one of these patients showed any signs of heart failure. The remaining four patients constituted the second group, and in them the abnormal rhythm was observed over periods of between one and twelve months. Cardiac failure appeared in two patients. The authors have found that in prolonged paroxysms a relative tolerance is established, and that even if failure does not supervene, signs of circulatory embarrassment are apt to appear on the third or fourth day after the establishment of abnormal rhythm. Among these signs are engorgement of the liver, transient albuminuria, and dyspnœa on exertion. Many patients suffering from prolonged tachycardia have been able to continue their occupations without discomfort. Bouveret is cited as originating the belief that failure begins to appear after a few days and progresses inevitably to a fatal termination. On the other hand, the fact that the liability to failure does not depend upon the duration of the paroxysm has been demonstrated in the cases described by Janicot, Vaquez, and Lewis, in addition to the authors' present series. It is suggested that the variable tolerance of the heart to attacks of paroxysmal tachycardia depends largely upon the extent of underlying myocardial damage, the rate and constancy of the new rhythm, and the age of the patient.

259. Birth-marks as a Site for Vaccination.

HANSEN (*Ugeskrift for Laeger*, September 26th, 1929, p. 827, and January 2nd, 1930, p. 16), since his appointment as vaccination officer in 1885 in his district, has made a practice of vaccinating all the angiomas he found in children coming to him for vaccination, the only exceptions being when the parents refused—a rare event—and when the angioma was situated near the eyes. He has kept records of these vaccinations from 1890 onwards; the average yearly number was about 6. The healthy skin around the birth mark was scratched, and its surface was very lightly scratched to avoid much bleeding. Among approximately 260 cases thus treated there was not a single instance of troublesome inflammation after the vaccination, the scar of which persisted. In the light of this experience the author challenges a statement by Oluf Thomsen in a recently published book on vaccination in which he says: "Vaccination of birth-marks with the object of making them disappear is absolutely objectionable." Hansen questions the validity of this sweeping verdict, and points out that by his procedure a double advantage is gained.

Surgery.

260. Sarcoma of the Thyroid Gland.

I. ARONS (*Annals of Surgery*, January, 1930, p. 44) states that malignant disease of the thyroid gland is infrequent, epithelial tumours predominating over those of mesoblastic origin. Thyroid malignancy occurs most frequently in districts where endemic goitre is prevalent, and develops in the majority of cases in goitrous subjects. Chronic irritation produced by foci of degeneration in old colloid goitres may induce parenchymatous or stroma hyperplasia, occasionally resulting in carcinoma or sarcoma respectively. Other etiological factors are trauma, a previous inflammation of the gland, or the injection of various irritants into large thyroids. Unlike benign goitre, where females outnumber males in the proportion of seven to one or even ten to one, sarcoma of the thyroid affects both sexes equally, the average age being 53. Diagnosis of sarcomas and carcinomas of the thyroid is difficult until the capsule of the gland is perforated by the growth and it is clinically impossible to distinguish between the two forms of malignancy, though in the case of sarcoma the rate of growth and approach of death are much more rapid than in carcinomas, the usual expectancy being only

two or three years after the inception of the disease. The first sign of cancer of the thyroid is a change in the primary benign goitre, which usually becomes hard, bossy, nodular, and irregular, and grows rapidly in size. Hard palpable lymph nodes may be present and may be removed for histological examination. Other symptoms may be the enlargement of subcutaneous veins over the tumour or fixation of the tumour to the skin, with tremor, palpitation, loss of weight, tachycardia, and increased metabolic rate in some cases. Dyspnoea, a frequent symptom, is produced by sabre-sheath stenosis of the trachea; the sarcoma may penetrate the trachea and give rise to the presence of blood in the expectoration. If the growth begins on the posterior aspect of the thyroid a dysphagia frequently develops, due to direct attachment to the oesophagus. Pressure of the growth upon the cervical sympathetic nerves, or infiltration of the sarcoma in the region of the carotid sheath, may produce paralytic miosis, loss of the pupillary reflex, unilateral facial hyperaemia and sweating, enophthalmos and narrowing of the palpebral aperture. Fever, as high as 102.5°F., is more common with sarcoma than with carcinoma. Sarcomas may be of the mixed round and spindle-cell, lymphoid, or round-cell types, with the greatest number of mixed cells. Surgical treatment can only be palliative, but tracheotomy and lobectomy in some cases prevent or delay death by the local effects of the tumour. Radium and *x* rays have been used, but although the initial response may be favourable the sarcoma rapidly metastasizes by the blood vascular system to the thoracic and abdominal viscera.

261. Enterocystoma.

RUTH E. MILLAR and G. ROBERTSON (*Brit. Journ. of Surg.*, January, 1930, p. 373) describe a case of enterocystoma in a girl, aged 8, who had suffered from attacks of severe sickness for four years. Each attack lasted twenty-four hours, and was sudden in onset and termination, with an interval of only one month latterly between the attacks. During the last four months these had become increasingly severe and frequent, with bile-stained vomiting, and pain in the right iliac fossa and epigastrium. The child was admitted to hospital for an operation for appendicitis. When the abdomen was opened an elongated, tense cystic tumour was found superimposed upon the caecum, the long axes of the tumour lying parallel to the intestine. The sausage-shaped mass, which on its deep aspect was connected for two-thirds of its length by a mesentery to the true mesentery of the ileo-caecal angle, was typically intestinal in appearance and exhibited peristalsis. Both ends were blind, with a constriction near the middle, and the end which pointed to the hepatic flexure was larger and more bulbous than the other, which overlaid a normal appendix. The inferior aspect of the bulbous end was attached by a band to a pericolic membrane enclosing the ascending colon and blending on the lateral aspect of the gut with the parietal peritoneum. After removal of the cyst peristalsis could be stimulated in it for two hours by means of warm, moist gauze pads. The cyst, which was unilocular, was found to contain 2 ounces of a transparent viscous mucoid fluid; it was 11 cm. in length, the maximum girth being 10 cm. The authors remark that these tumours are difficult to diagnose, and may be symptomless, though vague abdominal pain and recurrent attacks of vomiting are common. They occur most often in young females, and may become malignant, causing persistent ascites. Treatment must consist in the removal, with resection of the intestine if necessary. In the present case the cyst was separated from the bowel, with a mesenteric pedicle which made removal a simple operation. It is suggested that progressive hypertrophy of the muscle coat of the enterocystoma during four years explained the increasing severity of the attacks; tension of the cyst from increase of content would excite an attack by supplying the stimulus to the hypertrophied muscular coat.

262. Intussusception of the Ileo-caecal Angle.

INTUSSUSCEPTION of the ileo-caecal angle is only possible in cases where the mesentery of the ascending colon is sufficiently free; it is met with particularly in children and infants. J. VIDLICKA (*Bratislavské Lekárske Listy*, January, 1930, p. 3) believes that the cause is most frequently some pathological change of the intestine, such as a benign tumour, enteritis, or intestinal parasitism. The mechanism is explainable on the spastic theory of Nothnagel and Proping. The most important clinical symptoms are ileus, blood in the stools, and swelling in the right epigastrium. The abdomen remains soft, and the temperature need not be high. An *x*-ray examination reveals stenosis of the distal ileum and a narrow ring in the ascending colon. At the beginning of the illness, if the surgeon finds no other changes except oedema of the intestinal wall, simple devagination and fixation of the caecum suffice. In cases of gangrene or adhesions resection of the affected part is necessary.

Therapeutics.

263. Serum Treatment of Scarlet Fever.

F. VAN BORMANN (*Jahrb. f. Kinderheilk.*, December, 1929, p. 1) records his observations on 694 cases of scarlet fever treated with antitoxin and 292 controls. The dose used was always 25 c.cm. of unconcentrated or 10 c.cm. of refined antitoxin, and, except in the severest cases, a repetition of the dose was not necessary. The weight and age of the patients were not taken into consideration. The injections were given intramuscularly, except in the severest cases, which had intravenous injections. In the majority of the cases the antitoxin used was that supplied by the Behring works at Marburg, but a weaker Vienna serum, an American serum, and a Saxon serum were also employed. The cases fell into three groups: (1) a toxic group in which the initial symptoms were pronounced, including a subgroup of fulminating cases; (2) a very mild group, in which the toxic and septic symptoms of the initial stage were ill-marked and the temperature did not rise above 101.3°; and (3) a septic group, in which the clinical picture was characterized by complications from the first. The onset of desquamation did not appear to be affected by the injections unless perhaps it was a little accelerated. No influence, however, was noticed on its duration or character. In the toxic cases the temperature curve was the best indication of the action of the serum, especially as the fall of temperature was accompanied by general improvement in all the toxic symptoms, such as rapid pulse, malaise, and cerebral manifestations. As a rule there was a rapid fall of temperature to a subfebrile level within twelve to twenty-four hours after injection; the throat condition also showed a considerable improvement. A comparison of the temperatures of cases treated by serum with those of untreated cases showed only a distinct difference when the serum was given before the fourth day of disease. When the serum was given later the temperature curves were identical in the treated cases and the controls. Seven fulminating cases which were not treated by serum were all fatal, whereas out of 14 in which serum was given 5 recovered. In 4 of the 9 fatal cases the patients were moribund on admission and died a few hours after injection; another 2 died of lobar pneumonia five days after injection, and the other 3 died of toxaemia, in spite of serum given fairly early in the disease (third and fourth days).

264. Carbon Dioxide Inhalation in Pneumonic Atelectasis.

IN view of the lack of progress in the prevention and cure of pneumonia, contrasting with that in other diseases, such as typhoid and diphtheria, it has been suggested that there must be some special factor in pneumonia which is at present unrecognized and untreated. YANDELL HENDERSON, H. W. HAGGARD, P. N. CORYLLOS, and G. L. BIRNBAUM (*Arch. Int. Med.*, January, 1930, p. 72), who advocate the treatment of pneumonia by inhalations of carbon dioxide, maintain that there is such a factor—namely, occlusion of an affected organ and lack of drainage. When an air tube becomes closed all the protective mechanisms for clearing the lungs, such as the cough reflex, are incapacitated. The air in the occluded portion of the lung is soon absorbed, and the alveoli become deflated, collapsed, and gradually filled by secretion. In pneumonia it is the blocking of the lung air passages, bronchi, or bronchioles, by plugs of thick, sticky secretion which is the critical pathological factor in the production of atelectasis (termed apneumatosis by Coryllos) and the conditions characteristic of an undrained infection. Before birth the lungs are normally atelectatic, and if they are not fully distended soon after birth, pneumonia is likely to develop. It is known that, after surgical operations, massive lobar or lobular atelectasis of the lung is a rather frequent occurrence, and is the condition from which post-operative pneumonia develops. This atelectasis is prevented and relieved and the risk of pneumonia eliminated by the inhalation of an oxygen mixture containing carbon dioxide. The inhalation of 5 per cent. carbon dioxide, now the standard treatment for carbon monoxide poisoning, is also an effective preventive of post-asphyxial pneumonia, and of the asphyxia of the newborn. Experiments on dogs reported by the present authors demonstrate that atelectasis and pneumonia, artificially induced in these animals, are overcome by inhalation of this gas. The authors report that several hundred patients with pneumonia have been treated with oxygen and 5 per cent. carbon dioxide. In one series of 126 cases only 9 patients died, while a number recovered by crisis immediately after the inhalation. Nearly all the patients treated early recovered, and the deaths were practically limited to cases in which this treatment was introduced late in the disease. In a larger series of cases not so treated the mortality was 31 per cent. The authors

conclude that success depends on commencing the inhalation of carbon dioxide as early as possible, and believe that the results will be as effective as those obtained in post-operative and post-asphyxial pneumonia.

265. Treatment of Diabetes Insipidus by Pituitary Insufflation.

BOISSERIE-LACROIX and A. CHOAY (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, December 20th, 1929, p. 1005) report a case of a boy, aged 7 years, with diabetes insipidus which was successfully treated by powdered pituitary substance. The daily amount of urine averaged at first 7¾ pints, and in spite of negative radiographic, ophthalmic, and Wassermann examinations, antisyphilitic treatment was tried without any improvement resulting. Injections of the posterior lobe of the pituitary gland were then given, with great diminution of the polyuria and thirst. As the hypodermic injections were painful, intranasal insufflation of the powdered posterior lobe was substituted for them, the daily dose being approximately 1 grain. The patient continued this treatment for a year, with remarkable improvement in his general condition; the weight increased by nearly 9½ lb., and the quantity of urine passed in twenty-four hours fell to 35 to 53 oz. It is stated that A. and L. Choay have treated twenty cases of diabetes insipidus by intranasal administration of the powdered posterior lobe; they believe that this method has all the advantages of hypodermic injections while being painless, and therefore particularly applicable in children and in cases in which the daily polyuria does not exceed 25 to 35 pints. The only contraindication of this treatment is any pathological condition of the nasal passages.

Neurology and Psychology.

266. Skin Reactions in Neurological Conditions.

THE skin is innervated by both sensory and sympathetic nerve fibres, and the general effects of destruction of each type of nerve are well known. Sometimes, however, it is difficult to decide where the damage lies, whether in the nerve, the ganglion, or central to this. K. E. HARRIS (*Brain*, December, 1929, p. 484) describes two simple tests which easily determine whether the peripheral sensory and sympathetic nerve fibres are degenerate or not. The sensory nerve test is performed by inflicting a suitable injury, such as a needle scratch. When normal skin is injured a triple response of the blood vessels ensues. At the site of injury a spot appears (local vaso-dilatation), followed by whealing (local oedema); around the wheal is a flare (reflex arteriolar flare), and it is this flare that is of interest in nerve lesions. In a patient pre-existing anaesthesia of more than a week's duration, if a flare appears on the anaesthetic skin after injury the peripheral sensory nerve fibres are intact and the anaesthesia is either due to a lesion central to the dorsal root ganglion or is hysterical in origin. If the flare fails to appear, the peripheral sensory fibres are degenerated. The sympathetic nerve test is performed by faradizing the skin. Erection of the hairs may be produced by a reflex through the central nervous system, and Lewis and Marvin have shown that goose-skin appears around the electrodes if the skin is stimulated by a strong faradic current. This is due, not to a central reflex, but to the spread of nerve impulses along a plexus of sympathetic fibres in the skin. The absence of this local reaction to faradism indicates degeneration of these fibres. The application of these tests is illustrated in a case of sarcoma of the first rib, complicated by a cervical sympathetic paralysis, and later by paraplegia.

267. The Mechanism of Epileptic Fits.

A. SALMON (*Studium*, January 1st, 1930, p. 9) reviews the evidence for the existence of a vegetative epileptic centre situated in the diencephalic region, possibly connected with the infundibulum, and liable to react to toxic, reflex, endocrine, and emotional stimuli. Demole has shown that while depression of the infundibulum by calcium chloride results in sleep, its stimulation by potassium chloride produces motor responses and epileptiform seizures. Electrical stimulation of the pituitary body, owing to its contiguity with the infundibulum, gives rise also to severe convulsions, as does any sudden increase in tension in the third ventricle. The deep sleep which follows the seizure has lately been explained as due to depression of the infundibulum. Hypnotic drugs with a selective action on this centre have proved very useful in epileptic treatment. The functional relations of the infundibulum with the pituitary body may also explain the frequent association of diseases of the latter with epileptiform seizures, such as occur in pituitary and infundibular tumours, acromegaly, Simmonds's syndrome, and dystrophia adiposo-genitalis, during the treatment of many cases of epilepsy with pituitary extract. Supporting evidence is afforded by the deficiency of pituitrin in the cerebro-spinal fluid of epileptic patients, the occurrence of seizures after removal of the pituitary body, and the lesions of this gland found at necropsies. An epileptic centre in the diencephalon may also account for the frequent association of hyperthermia and seizures, due probably to irritation of the tuber cinereum. The ventricular situation of such a centre, specially sensitive to alterations in the cerebro-spinal fluid, explains the part played by these in the mechanism of epilepsy better than the hypothesis that the fluid acts by transmitting epileptic toxins. Salmon adds that meningocortical lesions may bring about changes in the cerebro-spinal fluid, and, by diminishing inhibition of the lower centres or in some other way, producing a cerebral vasomotor reaction which may affect the vegetative centre of the diencephalon, and initiate an epileptiform fit. Epileptic seizures of endocrine origin can also be explained on the grounds of the physiological relations of the various glands with the pituitary body, and the consequent reaction on the diencephalic-pituitary system. The existence of such a centre may also throw light on the seizures occurring in epidemic encephalitis and those consequent to emotional factors. The author concludes that, while the infundibulum is not the only centre concerned, the fit being a violent reaction of all the cerebro-spinal centres, it is certainly the starting point of the epileptic impulse which determines the seizure.

268. Cavernous Epidural Angioma.

W. T. CONNELL and W. D. HAY (*Canadian Med. Assoc. Journ.* January, 1930, p. 75) report a case of cavernous angioma of the epidural space in a woman, aged 31, which resulted in compression of the spinal cord. The first clinical signs appeared in 1918, when stabbing pains were felt over the lower ribs on the right side, followed a little later by involvement of the other side. Treatment for intercostal neuralgia was unsuccessful. The right foot began to drag while walking, and some weeks later the left foot became similarly affected. The condition progressed, and at the end of 1918 the patient was confined to bed, a diagnosis of spastic paraplegia being made. Two years later she was paralysed from the waist downwards, but retained perfect use of the upper part of the body; the legs were not wasted, but all power of voluntary muscular movement was lost. The knee- and ankle-jerks were exaggerated, and a positive Babinski sign was present in both legs. Tactile pain and temperature sensations were completely lost on the right side two inches above the umbilicus, and also on the left leg and back of the thigh. There was loss of control over the bladder; the reflexes and sensations of the upper part of the body were normal. The Wassermann reactions of the blood and spinal fluid were negative, and the fluid was under low pressure; there was no increase in its globulin content, and the cell count was 8. A diagnosis of spinal compression due to a slow-growing tumour was made, but the patient refused to have laminectomy performed. In 1921 the anaesthesia on the left side became absolute and reached the same level as on the right side. The patient eventually died in 1929 from cystitis and pyelonephritis. A vascular tumour was found in the epidural space at the level of the sixth and seventh vertebrae, involving the laminae and to some extent the roots of the arches, but leaving the bodies of the vertebrae free. The spinal cord at this level was compressed so that nothing but the meninges remained for a distance of 3 centimetres. Histological sections of the cord below the lesion revealed destructive changes in the pyramidal tracts and the columns of Goll and Burdach. The authors think that the angioma originated from the plexus of veins in the epidural space. They have been unable to find any similar record in the literature.

Obstetrics and Gynaecology.

269. Endometriosis of the Bladder.

ACCORDING to B. OTTOW (*Zentralbl. f. Gynäk.*, December 7th, 1929, p. 3330) endometriosis of the bladder resembles that of the umbilicus, inguinal canal, or abdominal operation scar in that menstruation leads to pain, increased tenderness, and increased congestion in the tumours, and sometimes to bleeding from them. Clinical details are given of cases in which, apart from operation, such symptoms permitted the diagnosis of heterotopic endometriosis in an abdominal scar or in the posterior vaginal fornix. Ottow believes that a similar history, combined with characteristic cysto-scopic findings, should lead with certainty to diagnosis of endometrioid tumours presenting in the bladder. In J. Müller's case (*Arch. klin. Chir.*, 1927) a bullous oedematous swelling containing blood cysts pushed forward the vesical mucosa near a ureteral opening, and was much larger and more congested during the menstrual period; the tumour was

regarded as a cavernous angioma, but was proved microscopically after removal to be an endometrioma. Ottow describes two cases in which women, aged 43 and 29 respectively, complained of dysuria preceding the menses by a day or two and completely disappearing a week afterwards; the cystoscopic appearances (during and between the menses), which are illustrated in colour, corresponded with those of Müller's case. A diagnosis of endometrioma was made, and was confirmed in the second case by histological examination of the tumour excised from the utero-vesical space. In the first instance the patient, an older woman, was treated by *x*-ray ovarian castration. After the ensuing menstruation the dysuria ceased and the size of the tumour, as determined cystoscopically, diminished; the blood cysts, however, persisted. Cases of vesical endometriosis hitherto recorded number about fifteen. Ottow emphasizes the diagnostic importance of cystoscopy, and regards the removal of a tumour fragment for biopsy as unnecessary and possibly harmful. A. PLAUT (ibid., p. 3358) records the case of a nullipara, aged 28, who had complained for a year of dysmenorrhœa and of dysuria during menstruation, and was found to have a small fibroid as well as adnexal adhesions. At operation a tumour was found infiltrating the posterior vesical wall, and was removed locally. More radical excision was not undertaken because the history was thought to point to endometrioma, a diagnosis afterwards confirmed microscopically. Endometrial tumours were not found elsewhere.

270. Radium and Surgery in Uterine Cancer.

F. A. MAGUIRE (*Journ. Coll. of Surgeons of Australasia*, November, 1929, p. 243) gives a brief preliminary report of some patients treated for a year at the Radium Clinic of the Royal Prince Alfred Hospital, Sydney, and reports in detail eleven of the cases. The series included patients whose condition might have been regarded as operable from the beginning, those apparently inoperable, those who had been operated on and whose condition had been considered totally inoperable, and those cases rendered operable by the use of radium. Two patients, both of whom had very advanced malignant disease, died; in six patients the growths may be regarded as being held in check, while two patients, on whom panhysterectomy was performed, are apparently clinically free from disease. For the purposes of radium treatment Maguire classifies cases in three groups: those considered to be operable; those which when first seen would be considered inoperable; and borderline cases which, at first apparently inoperable, may be rendered operable by the use of radium. In the first group of operable cases the condition is rendered much more favourable for operation if radium is used, for this will clear up the primary growth, allow the cervix to heal, and give a clean field for operation. In the second group of hopelessly inoperable cases radium will definitely check the immediate haemorrhage, stop the discharge, and, temporarily at any rate, stop the absorption of toxins by dealing with the growth locally. The patient immediately improves, loses her toxaemia, and is rendered more comfortable. Life is prolonged and suffering relieved. The same effects are obtained by the use of radium in borderline cases, and often operation becomes at least feasible. If an operation is performed within three months of the application of radium little extra difficulty is experienced from fibrosis. Pain, when due to the infiltration from the primary growth, is definitely relieved by the application of radium. Regarding the dosage and types of application, Maguire believes that when it is desirable to clear up a local condition and render it operable a massive dose over a short period is indicated, while in inoperable cases where it is desired to give a maximum amount of relief small doses over long periods are more appropriate.

271. Bimanual Gynaecological Examination.

L. FRAENKEL (*Münch. med. Woch.*, January 10th, 1930, p. 53) emphasizes the value of using the hands alternately for both vaginal and rectal examinations in gynaecological conditions, since much more accurate information about pelvic tumours palpated through the vaginal wall and fornices can be obtained if the right hand is used for the right side of the pelvis and the left hand for the left side; the awkward position which the right hand has to assume when palpating the left fornix, and vice versa, diminishes its sensitiveness. In a case of tenderness in the right iliac fossa, when there is difficulty in deciding whether there is a lesion in the appendix or in the Fallopian tube, he recommends the following manœuvre to separate the structures. The right adnexa are palpated bimanually in the usual way, and are then held downwards against the posterior wall of the pelvis by the left hand through the abdominal wall, while the right hand is removed from the vagina and palpates McBurney's point. If this is now found to be tender, while the mass lower down under the left hand is not, evidence is obtained in favour of an appendicular rather than a genital lesion, and vice versa.

Pathology.

272. Symptomless Infections in Monkeys Inoculated with Yellow Fever.

A. PETTIT and G. STEFANOPOULO (*C. R. Soc. de Biologie*, December 6th, 1929, p. 719) have encountered two instances in which monkeys inoculated with yellow fever virus developed a septicaemia without showing any symptoms of disease. The first monkey, *Macacus cynomolgus*, remained perfectly well for twelve days after inoculation; on the thirteenth day it appeared ill, and the following day it was killed. At necropsy there were no lesions suggestive of yellow fever. Nevertheless the blood of this monkey, withdrawn on the third day after inoculation, and again just before the animal was killed, produced typical yellow fever in two other macaques that were injected with it. The second instance concerned a *Macacus rhesus*, an animal that is more susceptible to yellow fever virus than is *M. cynomolgus*. This animal was inoculated with 7 c.cm. of a filtered suspension of infective liver, the injection being made intraperitoneally and into the liver. The animal remained perfectly well till thirty-six days after inoculation; it suddenly died without any warning symptoms. Post-mortem examination revealed a slight yellow discoloration of the cartilages, and a typical chamois yellow liver; the lungs appeared normal. Sections of the liver and kidney showed the usual fatty degeneration. The blood of this animal was tested thirty days after inoculation for the presence of neutralizing antibodies, with a negative result. The authors consider that the investigation of these "non-apparent" infections should be carried out in human beings, particularly among the indigenous population of yellow fever districts.

273. Blood Examinations in Achylia.

A. BORGBJAERG and M. C. LOTTRUP (*Acta Med. Scand.*, December 30th, 1929, p. 539) found that 50 per cent. of persons with achylia gastrica suffered with anaemia, usually slight and of simple type. The colour index was above 1 in 22 per cent. of the cases, megalocytosis was present in 15 per cent., and frequently the haemoglobin percentage was raised. Megalocytosis may occur with a colour index less than 1. With a positive Congo red reaction megalocytosis is rare; it is always present in pernicious anaemia, but not in cancer of the stomach. The size of the red cells varies in the same patient, and may increase with arsenic or iron treatment; liver diet frequently, but not always, removes the megalocytosis. By careful blood examinations of achylic patients it may be possible to detect early cases of pernicious anaemia. Patients with gastric ulcer and achylia have shown after gastrotomy the blood picture of pernicious anaemia.

274. Resistance of Haemolytic Streptococci to the Bactericidal Action of the Blood.

R. HARE (*Brit. Journ. Exper. Path.*, December, 1929, p. 375) finds that the ability of virulent strains of haemolytic streptococci to grow in normal human defibrinated blood varies with the age of the culture from which they are taken. (The term "virulent" is defined on a purely *in vitro* basis, and is used to denote streptococci from a 16-hour hydrocele fluid broth culture that are able to withstand the bactericidal action of normal human defibrinated blood sufficiently to be able to multiply in it after 1 to 3 hours.) Working with a virulent strain that had been passaged through mice, it was found that organisms taken from a culture 4 to 46 hours old were able to multiply in normal blood, whereas those taken from the same culture after 88 and 112 hours were unable to do so. With a rather less virulent strain multiplication occurred with organisms from a 12-hour but not from a 29 to 120-hour culture. With an avirulent strain no multiplication occurred at all with organisms taken from a 6 to 75-hour culture. Experiments on phagocytability indicated that if normal human serum was inoculated from a 16-hour broth culture of a virulent strain the organisms during at least the first 3 hours of growth proved highly resistant to phagocytosis. If the inoculum was made from a 32-hour culture the organisms during the first hour of growth were fairly susceptible to phagocytosis, but after 3 hours they became resistant. When the inoculum was made from a 72-hour broth culture the organisms developed only a slight degree of resistance to phagocytosis. The author concludes that haemolytic streptococci from broth cultures near the logarithmic phase of growth are better fitted to withstand the bactericidal action of normal human defibrinated blood than those from cultures in the decline phase. This is probably due in part to the ability of streptococci from cultures in the logarithmic phase to multiply faster than those in the decline phase, and in part to the assumption by growing streptococci of some degree of resistance to phagocytosis, which disappears when the organisms become senescent.

ASPIRIN DERIVATIVES

in RHEUMATISM, NEURALGIA, INFLUENZA, ETC.

We introduce and manufacture the following:

"MAGISAL"

PROMPT IN ACTION, AS BEING A SOLUBLE SALT (1 in 12, AGAINST ASPIRIN 1 in 400).

Bots. of 50 Tablets 2/6; 200 10/-.

"TYLCALSIN"

A further Soluble Salt

FOR USE ORALLY IN RHEUMATIC AFFECTIONS, CATARRH, NEURALGIA, AND FOR GENERAL RELIEF IN PAIN.

Bots. of 25 Tablets 2/6; 100 11/6.

"SEDASPRIN"

A compound of Aspirin and Bromine

CONTAINING 30.86% BROMINE IN 5-GRAIN TABLETS. SUGGESTED IN ALL FORMS OF NERVE TROUBLE, AND WHEREVER THE COMBINED QUALITIES OF ASPIRIN AND BROMIDE ARE INDICATED.

Bots. of 25 Tablets 2/6; 100 7/6.

"PHENYL-SEDASPRIN"

A NEW COMPOUND OF THE SALOL-TYPE EMBODYING THE THERAPEUTIC EFFECTS OF BROMINE, ASPIRIN, AND PHENOL.

Bots. of 25 Tablets 3/-.

"TYLLITHIN"

A very Soluble Salt of Aspirin

FOR USE PER OS AS AN ANTI-RHEUMATIC AND IN INFLUENZA, ALSO IN NEURALGIA, GOUT, AND AS A GENERAL ANALGESIC.

Bots. of 20 Tablets 2/6; 100 11/6.

"ASPRIODINE"

A compound of Aspirin and Iodine

CONTAINING 41.47% IODINE IN 5-GRAIN TABLETS. OF VALUE IN RHEUMATIC AFFECTIONS AND ARTERIO-SCLEROSIS.

Bots. of 25 Tablets 2/6; 100 7/6.

"PHENYL-ASPRIODINE"

EMBODIES THE ACTIVITIES OF IODINE, ASPIRIN, AND PHENOL. AN INTESTINAL AND URINARY ANTISEPTIC.

Bots. of 25 Tablets 3/-.

"METHYL-ASPRIODINE"

THE NEW ANTI-RHEUMATIC FOR INUNCTION

BALM 2/6. LINIMENT 2/6.

Samples of any of the above on request. *Write also for particulars of Peptone, Mercurome, and other Martindale preparations.*

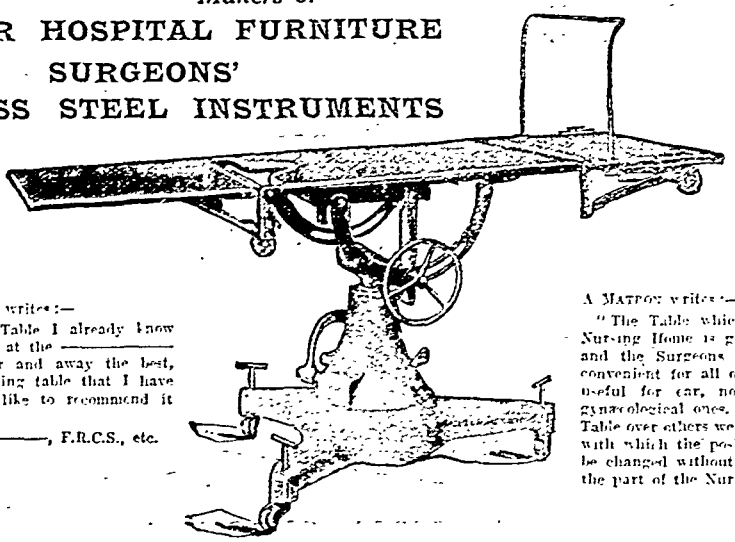
SURGICAL & HOSPITAL EQUIPMENT

by



ARNOLD & SONS

Makers of

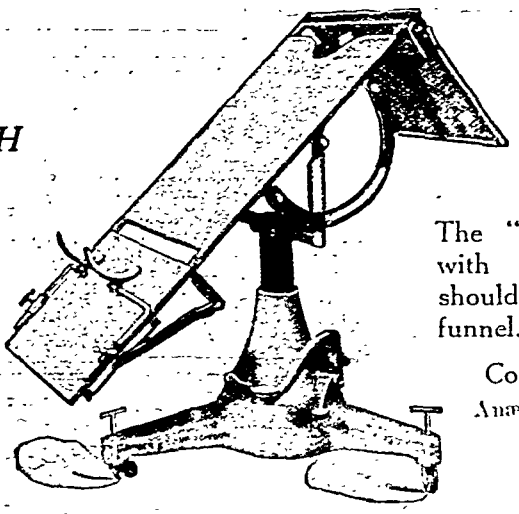
SUPERIOR HOSPITAL FURNITURE

SURGEONS'

STAINLESS STEEL INSTRUMENTS

A LONDON SURGEON writes:—

"Your Operating Table I already know well as we have one at the ——— Hospital. It is far and away the best, simple, cheap operating table that I have met, and I should like to recommend it very highly."



Signed, ———, F.R.C.S., etc.

A MATRON writes:—

"The Table which you supplied for my Nursing Home is giving great satisfaction, and the Surgeons who work here find it convenient for all operations. It is just as useful for ear, nose, and throat as for gynæcological ones. The advantage of your Table over others we have had is the rapidity with which the position of the patient can be changed without any strenuous work on the part of the Nursing Staff."

The "ARNOLD" PEDESTAL OPERATION TABLE

BRITISH MADE

The "ARNOLD" TABLE with lithotomy supports, shoulder rests, and douching funnel.

An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

SMOKE AND DISEASE

Smoke is perhaps the gravest danger to our national health.

Statistics show that about fifty per cent. of the time lost in workshops and offices in this country is caused by respiratory diseases due to the pollution of the atmosphere by smoke.

More than half the three-year-olds of this country have rickets, because they are robbed of sunlight by the smoke pall. The amount of sunlight has been found, by readings taken from various parts of England, to be in inverse proportion to the degree of air pollution.

About seven-eighths of the sun's power is shut off by smoke from the centre of London, and eighty tons of poisonous soot are emitted in the capital every hour.

The remedy lies in the burning of the smokeless fuels, gas and gas coke. The atmosphere is not polluted in the slightest degree either during their manufacture or their actual combustion.

Salvitae

Two sizes, 4/6 and 7/-.

Manufactured by American Apothecaries Co., New York.

A Remarkable advance in the presentation of H_2O_2

Also in exactly similar form and price—
SOLID IODINE

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.
Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.
A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 95, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

ACKERMAN-LAURANCE

"Brut-Royal"

"may be recommended with every confidence. By reason of its very low content of sugar it is specially suitable for persons with a rheumatic or gouty tendency."

A special food for changing the intestinal flora

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3.

Affords relief in all cases of high blood pressure

The daily exhibition of Sal Hepatica, the non-habit forming saline purgative, has proved of extreme benefit in all cases of high blood pressure. ¶ Sal Hepatica is also recommended as a rapid means of relieving the stress in cases of dysmenorrhœa. One or two drachms administered on the morning before the expected period, and again at its outset, rarely fails to relieve both the pain and depression. ¶ In chronic constipation the regular exhibition of Sal Hepatica for a week or two restores the daily habit of defecation. ¶ Sal Hepatica is not a "patent medicine" and is only advertised to the medical profession.

"Sal Hepatica"
TRADE MARK

the proved medical saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 39B.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.
This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.

Care should be taken to avoid clever imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

Greater Comfort for Your Patients.

"The Rose Corset-Belt"

which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 10/8 bottles.

Special Terms to Hospitals.

THE TREATMENT OF RHEUMATOID ARTHRITIS

THIS disease, which the medical man is increasingly called upon to combat, may be successfully treated by the correct application of Pistany radio-active Mud Packs.

The packs can be applied in the patient's own home if necessary, and the treatment may be successfully combined with other physiotherapeutic methods.

Pistany (Czecho-Slovakia) offers the most effective treatment for the cure of rheumatoid arthritis. The properties of Pistany's hot volcanic soft mud are quite peculiar. During the season over 26,000 visitors go to this picturesque Spa, and statistics show that of 100% of patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved.

Home treatment can never supersede the cure at the Spa.

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel.: Langham 1166.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) Ch.M.EDINBURGH. M.C.CANTAB. F.R.C.S.EDINBURGH. M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our classes.

¶ The Surgical Tutors of the College all hold either the M.S. Lond. or F.R.C.S. England, or both, and are highly experienced teachers.

¶ The Postal Courses are throughout clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S." free on application to the Secretary.

The Hospital for Sick Children,

Great Ormond Street, London, W.C.1.

A RESIDENT MEDICAL OFFICER is required at the COUNTRY BRANCH HOSPITAL, Tadworth Court, Tadworth, Surrey, on April 25th.

Gentlemen are invited to send in their applications to the Secretary, before 12 o'clock on Monday, March 31st, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for six months, but a successful candidate will be eligible for re-appointment.

Salary at the rate of £250 per annum, with board-residence in the Hospital, laundry allowance at the rate of £10 per annum, and, on re-election for a further period of six months, £18 18s. for the purpose of providing a substitute during annual leave of a minimum of four weeks.

Candidates must possess a legal qualification to practise, and must have held a responsible resident appointment at a General Hospital.

All candidates must be in attendance on Wednesday, April 2nd, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
March, 1930. Secretary.

Royal Albert Hospital and Eye INFIRMARY, DEVONPORT.

There will be a vacancy for an ASSISTANT HOUSE SURGEON (unmarried) on April 1st next.

Applicants must be fully qualified registered, and the appointment will be for six months. Salary £100 per annum, with apartments, board and laundry free.

Applications, stating age, accompanied by copies of not more than three testimonials, should reach the undersigned not later than Saturday, the 22nd instant.

By Order of the Committee,
FRANK ROWE,
March 10th, 1930. Secretary.

Macclesfield General Infirmary.

(100 Beds.)

Wanted at once, SECOND HOUSE SURGEON (male). Salary at the rate of £150 per annum, with board and residence. Anæsthetic experience essential.

The appointment is for six months, subject to one month's notice on either side.

Applications, stating age, nationality, and qualifications, with copies of testimonials, to be sent to the undersigned.

A. E. HONEYBURN, Secretary.

Peace Memorial Hospital, WATFORD, HERTS.

SECOND RESIDENT MEDICAL OFFICER (female). £150 per annum. Appointment for six months, eligible for renewal.

Applications, stating age and full particulars, with at least three recent testimonials, should be received later than March 24th by the undersigned. No canvassing permitted.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are *invited from fully qualified* Medical Practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital, Birmingham.

The Hospital accommodation is fixed by the Guardians at 926 beds, divided into Medical, Surgical, Children's, Infectious, Gynæcological, and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical Massage, and Sunlight Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that period.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work, and such other *duties as may be assigned* to them by the Chief Medical Officer, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A percentage deduction will be made from the salary and value of emoluments for *superannuation purposes*, and for this purpose the emoluments are valued at £230 per annum. *Fourteen days'* leave will be granted to the successful candidates during their term of office.

Further particulars of the appointments may be obtained from the Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and *qualifications, accompanied by copies of recent* testimonials, should be forwarded so as to reach me not later than Wednesday, March 19th.

Union Offices, Birmingham. February 28th, 1930.

C. P. BEECH, Clerk to the *Guardians.*

Borough of Bridlington.

APPOINTMENT OF MEDICAL OFFICER OF *HEALTH AND SCHOOL MEDICAL OFFICER.*

The Town Council of Bridlington invite applications for the appointment of Medical Officer of Health for the Borough, subject to the *provisions of the Public Health* (Officers) Act, 1921, and the Sanitary Officers Order, 1926.

The gentleman appointed will be required to perform all the duties imposed on a Medical Officer of Health, School Medical Officer, Maternity and *Child Welfare Medical Officer*, Medical Superintendent of the Infectious Diseases Hospital, and, act as Port Medical Officer of Health, and carry out all such duties as the Council, with the consent (if necessary) of the *Minister of Health*, may from time to time direct. He must reside in the Borough, and devote all his time to the duties of the office, and must not engage in private practice.

The appointment will be subject to the approval of the Minister of Health, and the salary to cover all the duties specified above will be *£800 per annum inclusive.*

Full particulars of the appointment may be obtained on application to the undersigned.

Applications, endorsed "Medical Officer," stating age, qualifications, and experience, accompanied by copies of not more than three *recent testimonials, should reach the* undersigned not later than Thursday, the 20th instant.

Canvassing, either directly or indirectly, will be a disqualification.

Town Hall, Bridlington. March 5th, 1930.

GEORGE MELVIN, *Town Clerk.*

Edinburgh Hospital for Women

AND CHILDREN,
Whitehouse Loan, EDINBURGH.

Applications are invited from qualified Medical Women for the post of JUNIOR HOUSE SURGEON at the above Hospital. The appointment *is for six months from April* 1st, with board, residence, and laundry.

Applications, with copies of testimonials, to be received by the Secretary on or before March 22nd.

Elsie Inglis Memorial Maternity

HOSPITAL,
Spring Gardens, EDINBURGH.

Applications are invited from qualified Medical Women for the post of HOUSE SURGEON for above Hospital. The appointment is for six months *from April 1st, with* board, residence, and laundry.

Applications, with copies of testimonials, to be received by the Secretary on or before March 22nd.

City of Nottingham.

APPOINTMENT OF RESIDENT MEDICAL SUPERINTENDENT,
NOTTINGHAM CITY INFIRMARY.

The Nottingham City Council invite applications *from* duly qualified persons (preferably married) for the appointment of Resident Medical Superintendent at the Nottingham City *Infirmary.*

Salary £900 per annum, rising (subject to *satisfactory service) by two annual increments* of £50 to a maximum of £1,000 per annum. An unfurnished house, with light, fuel, and laundry will be provided but this will not include food or servants.

The above-mentioned salary is inclusive of all duties and the person appointed will not be allowed to engage in private practice.

The appointment will be subject to the approval of the Ministry of *Health.*

Applicants, in addition to possessing the usual professional qualifications, must (1) have held the position of House Physician or House Surgeon in a *public General Hospital*, and (2) have had considerable experience as a Medical Officer in a Poor Law Infirmary or *similar Institution.*

Further particulars as to the terms of the appointment and of the duties to *be performed* in connection therewith may be obtained on application to me, the undersigned, and the successful candidate will be deemed to have had notice of and to have accepted such terms.

The appointment will be subject to the Superannuation Scheme in force, and the successful candidate will be *required to pass a* medical examination.

Applications, stating age, qualifications, and full particulars *of present and past experience*, together with copies (which will not be returned) of not more than three recent testimonials, endorsed "Resident Medical Superintendent," to be delivered at my office not later than *first post on Wednesday*, March 19th next.

Canvassing, whether directly or indirectly, is prohibited and will be deemed a disqualification.

Dated this 28th day of February, 1930.

Guildhall, Nottingham.

W. J. BOARD, Town Clerk.

Applications are invited from registered Practitioners. His duties will commence on June 1st. Salary £1,000 per annum.

Applications, to accompany not more than three testimonials, to be addressed to W. J. Morcom, Secretary, Office, 7, Fitzroy Square, London, W.1

County Council of Durham.

VENEREAL DISEASES MEDICAL OFFICER.

The County Health Committee invite applications for a Clinical Venereal Diseases Medical Officer at a salary of £750 per annum, rising by three biennial increments of £50 and a further one of £37 10s. to a maximum of £937 10s. per annum. Travelling expenses will be paid by the County Council.

The appointment is terminable by three months' notice on either side, and will be subject to the following conditions:

1. The officer appointed must be a registered Medical Practitioner, with not less than three years' experience in the practice of his profession subsequent to qualification, must devote the whole of his time to the duties of the office, and must not engage in private practice.
2. Applicants for the post of Venereal Diseases Medical Officer must comply with the following conditions which are laid down in Section 5 of the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, made by the Minister of Health under Section 59 of the Local Government Act, 1929:
   "Any person appointed by the Council of a County or County Borough to be a Venereal Diseases Officer shall be a registered Medical Practitioner, who, prior to the 1st April, 1930, has held the appointment of Venereal Diseases Officer with the approval of the Minister, or who (1) has had at least three years' experience in the practice of his profession subsequent to qualification, and (2) is in possession of a certificate, given by the Venereal Diseases Officer of a treatment centre at which not less than 500 patients attended for the first time during the 12 months preceding the issue of the certificate, testifying that he has attended at the treatment centre for a period of not less than three months and has received during that period not less than 130 hours' instruction in the modern methods of diagnosis and treatment of venereal diseases."
3. The holding of a Diploma in Public Health, and practical experience in Bacteriological laboratory work will be deemed additional qualifications for the post.
4. He will act under the directions of the County Medical Officer, and will be required to reside in the City of Durham or other approved centre.
5. He will be required to give instruction in modern methods of diagnosis and treatment to general practitioners attending the clinics.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination, as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, endorsed "Venereal Diseases Medical Officer," together with copies of not more than three recent testimonials, must be received by the County Medical Officer, Shire Hall, Durham, not later than the 29th instant.

Shire Hall, Durham. March 11th, 1930.

HAROLD JEVONS, Clerk of the County Council.

Kettering Urban District Council.

Candidates must be registered Medical Practitioners, and must be prepared to begin duties on May 1st. Salary for the Senior post at the rate of £150 per year, Junior at the rate of £100 per year, with board and residence in the Hospital.

Candidates are requested to state whether they are prepared to accept the post of Junior if not selected for the Senior office.

The appointments are for a period of six months only; at the end of that time the Junior will be eligible to apply for the Senior post, which then becomes vacant.

This Hospital is recognized by the University of London for the purpose of the M.D. and M.S.

Applications, stating age and qualifications, with copies of three recent testimonials, should be sent to me by Wednesday, March 26th.

W. COCKBURN, Supt. & Secretary.

A Surgeon is required for the EDINBURGH HOSPITAL FOR CRIPPLED CHILDREN, with Major and Minor Clinics in the South-Eastern area of Scotland. Applicants must be duly qualified Medical Practitioners who have wide experience of Orthopædic work. The Surgeon appointed will be required to confine his private practice to orthopædic surgery. The Lectureship of Orthopædics in the University of Edinburgh will be associated with this appointment. Total emoluments £1,000 per annum. Applications, with testimonials, should be sent to R. W. MARTIN, W.S., Hon. Secretary, Edinburgh Hospital for Crippled Children, 5, Hill Street, Edinburgh, from whom further particulars may be obtained. Applications must be lodged by April 12th.

General Hospital, Nottingham.
(377 Beds.)

A SECOND CASUALTY OFFICER (male) required at the above Institution. Candidates are desired to send applications, stating age, qualifications, and experience, together with copies of testimonials, to the undersigned, not later than Saturday, March 29th. Duties to commence on Friday, April 11th. The appointment is for six months. Salary at the rate of £150 a year, with board, residence, and laundry.

PETER M. MACCOLL,
House Governor & Secretary.

Freemasons Hospital and NURSING HOME,
237, Fulham Road, Chelsea, S.W.3.

By the resignation of the Physician-in-charge, the post of RADIOLOGIST at the Freemasons Hospital is vacant. Candidates are requested to state full qualifications and experience, and to lodge their applications on or before March 25th. For further information apply to the Honorary Secretaries.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

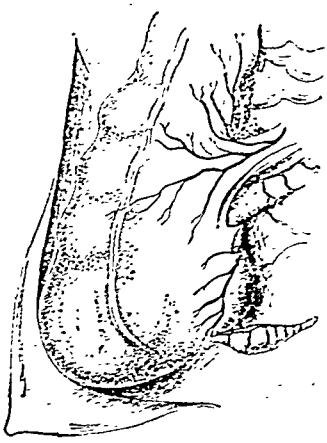
Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: TEMPLE BAR 1616 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.



1. PARTNERSHIP.—SUFFOLK.—Third share of old-established increasing Practice in small pleasant market town in good agricultural district. Cash receipts last year over £3,100, including appt. £500 and panel producing £500. Expenses light. Railway station. Compact house (consulting and waiting rooms, 2 sitting, 5 bedrooms, dressing room, bathroom, etc.). Garden. Garage. Price for freehold £900. Premium 2 years' purchase. Sport.
2. KENT COAST TOWN.—Popular Resort.—PARTNERSHIP.—A share representing over £1,000 p.a. is for disposal owing to the sudden death of the senior of four partners. Gross cash receipts for past 12 months £7,590, and increasing. Panel produces about £2,000 p.a. Suitable house, with 2 reception, 5 bedrooms, etc. Can be rented. Cottage Hospital, and scope for some surgery. Premium 2 years' purchase.
3. PARTNERSHIP.—WEST MIDLANDS.—The third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2,367 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £600 or £700. Premium 2 years' purchase. Excellent sport.
4. BIRMINGHAM SUBURB.—Well-established middle and working-class PRACTICE, offering large scope. Receipts for immediate past year nearly £1,200, including panel of 1,595. Low expenses. Exceptionally nice house, thoroughly modernized and redecorated. Contains 7 rooms, with dressing room, bathroom, etc. Good professional accommodation. Price for freehold £1,000, or can be rented on lease at £70 p.a. Premium £2,100.
5. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.
6. SOUTH-WEST OF ENGLAND.—Old-established and increasing PRACTICE in pretty district 5 miles from Hospital town and within 10 miles of the sea. Income last year £1,489, including Union, etc. (£105) and panel of 780. Railway station near. Detached house (professional rooms, 2 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Rent on lease £45 p.a. Premium £2,100.
7. LONDON.—EASTERN [illegible] good middle-class PRACTICE averaging [illegible] of 715. Fees 5/6 upwards. Not much [illegible] nice house, with large garden, tennis court, etc. Contains 10 rooms, in addition to bathroom, etc., and professional rooms. Two garages. Rent on lease £120 p.a. (upper part well let off). Premium £2,000.
8. WITHIN FIFTY MILES OF LONDON.—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 5/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (5 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Electric light. Price for freehold £5,000. Premium £1,050. Exceptionally good educational facilities for boys.
9. LARGE UNIVERSITY CITY (WEST).—Good-class old-established non-dispensing PRACTICE worth last year £1,274, including select panel of about 350. Visits up to 21/-. Very little midwifery. Good house in best part of City, overlooking park, with ample accommodation. Vendor's freehold, but will be let on lease. Premium only £1,200.
10. CAMBS.—Old-established Country PRACTICE, averaging for the past three years over £1,200 p.a. Panel of 870. Visits 5/- upwards, medicine extra. About 30 cases of midwifery from 2 to 3 gns. Nice house, with 2 reception, 6 bedrooms, etc., and garden. Rent on lease £80 p.a. Premium £1,800.
11. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.
12. PARTNERSHIP.—LONDON, S.W.—PLEASANT RIVERSIDE SUBURB.—A one-sixth share is offered in an old-established mainly better-class Practice, rapidly increasing, and with scope for still further development. Average gross cash receipts for past two years £6,213 (last year £6,662). Panel of over 5,000. Fees 5/6 to 21/-. Mid. 5 to 20 gns. Very good house, with 5 to 6 bedrooms, etc. For sale or might be rented. Premium 2 years' purchase.
13. LONDON, S.W.—Very old-established chiefly middle-class PRACTICE, rapidly increasing and offering still further scope. Gross cash receipts for the immediate past twelve months approximately £5,000. Panel of about 1,500; could be much increased. Fees from 2/6 to 21/-. Two houses available, on rental. Very suitable for two friends in partnership. Premium 1¼ years' purchase.
14. MIDLANDS.—Old-established good mixed-class PRACTICE in beautiful country district near large town. Receipts for last twelve months estimated to be £900, and increasing. Fees 5/6 to 20/-. Excellent house with all conveniences, containing 2 reception, 6 bedrooms, etc. Rent on lease £65 p.a. Premium £1,800.
15. SUSSEX.—Unopposed old-established Village PRACTICE in delightful surroundings, producing about £1,100 p.a., including panel of 545 and capable of considerable increase. Exceptionally charming residence standing in 3½ acres of well-laid-out garden, tennis court, etc. and containing lounge hall, 2 reception, 7 bedrooms (3 fitted h. & c. water basins, dressing and 2 bathrooms, etc. Central heating Electric light. Garage. Price, freehold, £3950. Premium £1,650.
16. YORKS.—LARGE TOWN.—Very old-established middle and working class PRACTICE, offering exceptional scope for increase. Income for last year £1,500, including panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £56 p.a. Premium £2,250.
17. HOME COUNTY.—Near Sea.—Old-established unopposed Country PRACTICE in pretty district. Receipts last financial year £1,115, including union, etc., £55, and panel 400. Railway station near. Good house in own grounds (about one acre, but more can be had if wished), containing 2 reception, 6 bedrooms, etc. Water laid on and electric light available. Price, freehold, £1,650. Premium £1,625. Educational facilities and sport.
18. LONDON, W.—Chiefly middle-class PRACTICE, averaging about £700 p.a., including panel of 750. Visits 5/6, 5/-. No midwifery. Suitable house, with 4 beds., etc. Rent on lease £95 p.a. Prem. £750.
19. PARTNERSHIP.—OXON.—Delightful residential district, near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,540, and offering good scope. Panel of nearly 1,000. Fees 5/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.
20. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea.—A half share in a very old-established and rapidly increasing mixed general Practice. Average cash receipts for last 3 years £2,727, last year £3,521. Panel of 1,130. Fees 5/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900, £1,200 on mortgage. Premium £2,300. Cottage Hospital, and good scope for major surgery.
21. NEAR LIVERPOOL.—Mainly better working-class PRACTICE, producing about £700 p.a., including panel of 854. Fees 2/6 to 5/-. Mid. 3 to 5 gns.; about 20 cases yearly. Suitable house available on rental. Premium £1,000.
22. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available, on rental. Premium £2,250.
23. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 380. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1½ years' purchase.
24. YORKS.—(North Riding).—Country PRACTICE in beautiful district. Average income over £750, including panel of about 330. Fees 5/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
25. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
26. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visits 5/- to 21/-. Panel of about 380. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' purchase.
27. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 5/- upwards. Not much midwifery. Low expenses. Very well situated double-fronted house, 2 reception, 4 bedrooms, etc., and good professional accommodation. Garden. Price for freehold £1,600 (£1,000 on mortgage). Premium 1½ years' purchase.
28. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,250, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,250, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.
29. SOUTH-WEST OF ENGLAND.—GOOD HOSPITAL TOWN.—A one-third share in an old-established mixed-class PRACTICE is offered owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. Low expenses. Commodious house, with garden and garage, rent £70 p.a. Premium 2 years' purchase. Vendor on staff of Hospital, and scope for surgery.
30. NEAR WORCESTER.—Old-established Country PRACTICE, averaging over £1,000 p.a., including panel of about 600. Fees 2/6 to 10/6. Good house, with ample accommodation. Rent on lease £35 p.a. Premium £1,350, £1,000 down, balance easy instalments.

ASSISTANT required for Town Practice in Leicestershire. Indoor, £150 p.a. Scotch Graduate preferred.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Among the Results of Constipation

Distended and sagging cæcum compressing and obstructing blood supply of vermiform appendix.

are not only the grave toxæmias of which much has been learned in recent years, but also conditions arising from mechanical factors, due to displacement of the viscera or pressure exerted by the distended bowel.

AGAROL Brand Compound, combining three essential actions: lubrication of the intestinal tract, restoration of the peristaltic force, and softening of the impacted fæces, generally aids in overcoming the effects of constipation. Gentle but forceful in action, Agarol Brand Compound assists the organism back to regular normal evacuation by restoring *peristaltic function*.

The dependability of Agarol Brand Compound has definitely enlisted the interest of the medical profession, who in most cases of acute or chronic constipation, successfully prescribe Agarol Brand Compound — one tablespoonful on retiring.

Emplets

Enteric-Coated Gland Products

IT is generally agreed that with the exception of thyroid most, if not all, of the gland preparations are partially, or wholly, destroyed by the gastric juice and that the hormones of these latter glands can only be made fully available by absorption after they have passed unaltered through the stomach.

The word **Emplet** designates enteric-coated endocrine gland tablets manufactured by Parke, Davis & Company. **Emplets** are not dissolved in the acid gastric secretion and, therefore, pass through the stomach unchanged into the small intestine, where the protective coating is rapidly dissolved and the active gland material is released and made available for absorption. Even in the case of thyroid our correspondence shows that the medicinal value of the gland is very much enhanced by its exhibition in **Emplet** form.

The enteric coating used for these tablets is the result of many years of research work in the Parke, Davis & Company Laboratories. It contains no salol and is therapeutically inert.

The following 'Emplets' are available:—

Corpora Lutea, 2 grs., *desiccated*	Parathyroid Gland, 1/10 gr. *desiccated*	Pituitary, Whole Gland, 5 grs., *fresh*
Orchic Substance, 5 grs., *desiccated*	Pituitary, Anterior Lobe, 2-1,2 grs., *desiccated*	Suprarenal Gland, 2 grs. *desiccated*
Ovarian Substance, 5 grs., *desiccated*		Thyroid Gland, 1-4 gr., 1 2 gr., 1 gr., *fresh*

Supplied in bottles of 25 and 100 (except Thyroid, in 100's and 500's only).
A booklet giving further details will be sent on request.

PARKE, DAVIS & COMPANY

50-54 Beak Street, London, W.1.

LABORATORIES: HOUNSLOW, MIDDLESEX.

Inc. U.S.A., Liability Ltd.

D

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital is now open for suitable general surgical cases at 17, Park Lane, London, W.1. The fees for a room cost now only two guineas a week, interest in the scheme having made possible three further reductions since it was started.

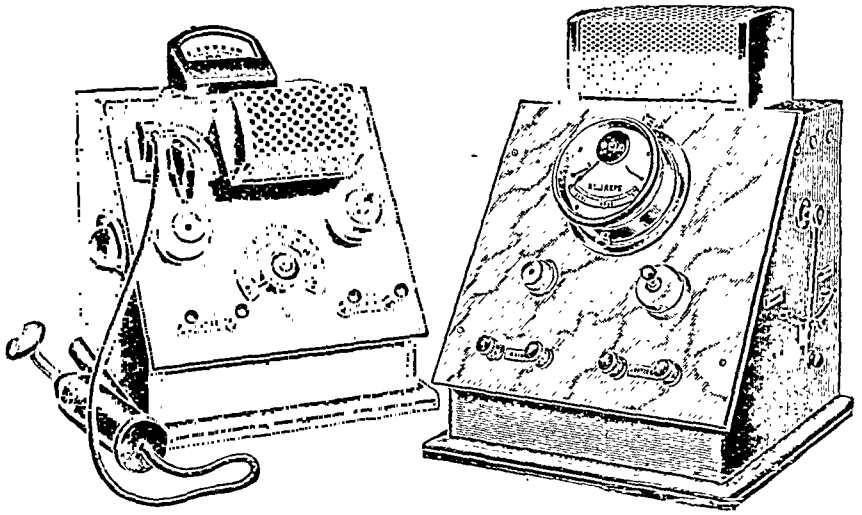
(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet at the same time to avoid any semblance of a charity which would be distasteful to such.)

Any further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: Grosvenor 2312 & 2313.

A TYPICAL SCALE OF REDUCED FEES FOR SURGICAL CASES IN THE ANNEXE CLINIC OF THE HAROLD FINK MEMORIAL HOSPITAL AT 17, PARK LANE.

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6 6 0
Dressings, Theatre Fees, etc.	1 1 0
Anæsthetic Fee	2 2 0
Surgical Fees for Major Operation (nominal fee only according to patient's means) ... ... (say, from)	15 15 0
(From Twenty-four guineas inclusive fee)	£25 4 0

N.B.—The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance.



When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic or X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced nominal fees only charged therefor.)

Telephones: Grosvenor 2312 & 2313.

All rooms are of course separate, and hold one patient only, there being no wards.

DIATHERMY APPARATUS
FOR THE GENERAL PRACTITIONER

Thermo-penetration or Diathermy Treatment is receiving extraordinary attention on the part of the medical profession owing to its manifold uses and the unquestionably satisfactory results obtained in treatment.

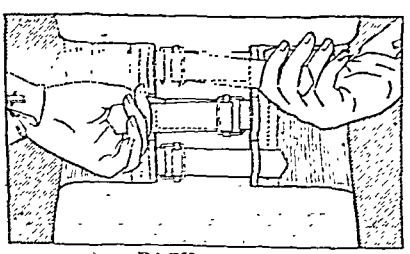
LATEST MODEL

THIS NEW *FLEXIBLE* SUPPORT

IS APPROVED BY LEADING SURGICAL OPINION

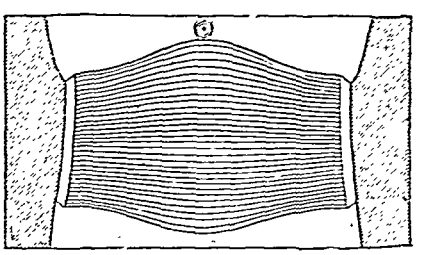
Brit. Pat. No. 279477.



Being Pliable, it Exerts a Firm yet Natural Compression without Restriction

The Linia Belt represents a definite step forward in modern surgical belt construction, and its patented principles are widely approved by leading professional opinion.

This belt, designed by anatomical experts, is the result of 25 years' research and experiment in making elastic supports to medical requirements. The efficiency and comfort of this method of abdominal control is vouched for by the many prominent medical men who have adopted the Linia Belt for their personal use.



THE ACTION OF THE LINIA BELT

The Linia Belt, being made entirely in an exceptionally tough elastic tricot, with firm back and strong extendible front, gives the firm and efficient support so necessary for post-operation wear *without employing any rigid components*. Thus it allows complete freedom in movement and breathing. Corpulence is reduced by a gentle massage action and a *natural* compression exerted which restores any displaced muscles and organs to their natural conformation. Recommended for post-operation wear in cases of Intestinal Ptosis, Enteroptosis, Visceroptosis, Gastroptosis, Nephroptosis.

BACK VIEW.

The tough, live horizontal elastic of this special tricot can be regulated to the required tension by means of slide buckles. Thus its lifting and massaging powers are easily controlled. As the abdomen resumes its normal conformation, further adjustments of the slide buckles can be made.

FRONT VIEW.

At the front of the belt, the thin tricot of great strength can be extended to the required depth, so that a gentle pressure is exerted on the full area of the abdomen.

Pressure is applied from pubis to groins as a safeguard against rupture.

We invite you to submit this belt to your own tests

We shall be pleased to forward a Linia Belt for your inspection free of charge. *POST ORDERS* can be carried out to your direction on receipt of exact measurement round girth and required depth from pubis upwards. Standard depths, 9, 10, and 11 inches. *Prices:* Standard Model, 2½ guineas. In black, thread and elastic, 3 guineas; in pure silk and elastic, 6 guineas. Post free in United Kingdom.

The Linia Belt

is on sale only at

J. ROUSSEL, 173, Regent Street, W.1 (*Special Branch for Men's Abdominal Belts*)

SOLID IODINE

A Remarkable advance in the presentation of H_2O_2

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10 volume strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

Local Anæsthesia in Surgical Practice

OBLIQUE FRACTURE OF THE HUMERUS.

TYPICAL CASE.

D. H. D., aged 24 years.

Diagnosis: Oblique fracture of the humerus.

Operation: Reduction by closed method.

Anæsthesia: Brachial blocks.

History: Patient entered hospital with a fracture which had been sustained two hours before his examination. The left humerus showed a spiral fracture with considerable shortening.

Anæsthesia: Brachial anæsthesia, using 10 c.c. of a 1 per cent. Novocain-Adrenaline solution.

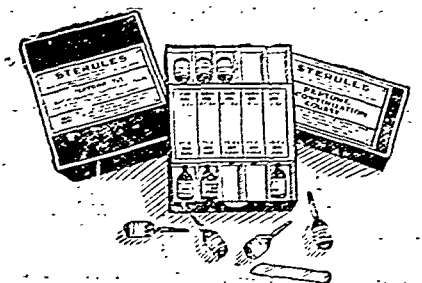
Operation: Reduction was made directly under the fluoroscope and a modified Thomas splint applied. The patient was allowed to leave the hospital thirty minutes after entering.

—EXTRACT FROM PRACTICAL LOCAL ANÆSTHESIA (FARR).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.



Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

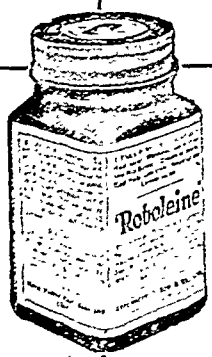
M.C.14

Unique stability of Lysolat in Salt solutions

Antiseptics have so often to be used in the presence of organic matter that the effect upon them of various salts (the chlorides in particular) is a vital factor in their germicidal efficacy.

The illustration shows a 10 per cent. solution of various lysols and other common or proprietary antiseptics, in water to which 3 per cent. of sodium chloride has been added. It will be seen that No. 1 (Lysolat) alone preserves a perfect emulsion, the others having been broken up and their antiseptic qualities destroyed.

Medical Men will realise the significance of this test. It is well known that in the presence of certain emulsifying agents, free bacteria exert a buffering action upon clots of organic matter, breaking them up and liberating the bacteria within. The presence of a chloride greatly diminishes this disintegrating action and destroys the emulsion. Where the emulsion carries an antiseptic or disinfectant the latter is separated and rendered ineffective.



Experiment has proved that the cresol isomers tend to correct the depressing effect of chlorides upon the bacteria, but they can obviously prove germicidally efficient only in a state of perfect emulsification. Lysolats are composed of the most active and powerful of the cresols carried by an emulsifying agent of unique stability.

Lysolats (LYSOL TABLETS)

PATENT 118667

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Dicey St., London, S.E.1.

OVALTINE

PHOSPHORUS IN NEURASTHENIA

Although it is realized that much difference of opinion prevails in medical circles as regards the therapeutic value of phosphorus, it is not illogical to claim that where the element is indicated, as in the neurasthenias, its tonic and restorative effects are more likely to be produced from natural phosphorus nutrients, such as those in "Ovaltine," than from medicinal products.

In the majority of cases in which "Ovaltine" has been prescribed for its "phosphorus" effect—that is, for its tonic and restorative effect upon the nervous system—the results of its administration have been gratifying in the extreme.

"Ovaltine" has been used with marked success in neurasthenia of the type known as cerebral neurasthenia, or psychasthenia, a variety of which is induced by excessive mental labour, or by worry, anxiety, or nervous strain.

The delicious flavour of "Ovaltine" renders the product acceptable even to the most fickle or jaded palate, while its exceptional nourishing qualities exert a profound influence for good health.

A liberal supply for clinical trial sent free on request.

Calcium Deficiency in Expectant & Nursing Mothers

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to ensure adequate calcium retention.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

THERAPEUTIC PRODUCTS LTD. (Dept B.M.J.17), Napier House, High Holborn, London, W.C.1.

Dimol

in Enteric Epidemicity

Causation is always difficult, and often impossible, to discover, but it seems a reasonable procedure, in epidemic areas, to assist prevention by the use of an intestinal bactericide. Dimol is non-toxic to any part of the alimentary mucosa, yet one grain has a bactericidal potency for cultures of B. typhosus equal to thirty-five times that weight of pure phenol.

The Dimol Laboratories are prepared to demonstrate to any properly constituted committee of the Medical Profession that a pure culture of this bacillus can be swallowed, and the germs destroyed in the stomach by the action of Dimol pulverettes.

After long and thorough investigation, at the Royal Naval College, Greenwich, Dimol pulverettes are now supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

The Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Purity and Stability

Some years ago it was established that purity in anæsthetic ether was the essential factor—"*the purer the ether the better the anæsthetic.*"

Subsequent experience in practice has confirmed this; and the necessity for unassailable purity is now universally recognised.

The perfected process of manufacture and the method of packing adopted in the production and issue of Aether Puriss. B.D.H. ensure a degree of purity and stability hitherto never achieved in any anæsthetic ether.

Aether Puriss. B.D.H. is pure ethyl ether made from special duty-free spirit to which no methylating agent has been added; its original purity and mode of packing eliminate entirely the possibility of formation of aldehydes, peroxides and other oxidation products which produce toxic after-effects; hence its wide adoption in the principal hospitals throughout the world.

Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

BENGER'S FOOD, LTD., Otter Works, MANCHESTER.

BENGER'S Food

REGD. TRADE MARK.

'PANOPEPTON'

Ideal Food for the Sick.

Agreeable, highly Diffusible, Assimilable.

The patient or the nurse may stretch out a hand at any time, in the night or any daylight hour, and find in Panopepton a stimulating, fortifying food, especially "heartening." It more quickly and substantially relieves that "gone feeling" than anything else we know of.

Panopepton is a bright, rather dense, deep amber-colored fluid, with a characteristic bouquet, grateful to the palate and stomachic. The finished product contains 24 per cent. of total dry solids.

Panopepton is obtained by the physiological hydrolysis of the entire wheat berry and prime lean beef.

The original thought in Panopepton, fully realised, is that it shall present for the invalid the complex of nutritive material which only may be derived under the most favourable conditions of digestion.

Panopepton presents a complex of proteins now known to be essential, and for the greater part in the form of nitrogenous, non-coagulable proteins, all the extractives, savory and mineral substances of the prime lean beef and entire wheat berry; the wheat carbohydrates in the form of dextrose and maltose.

All these considerations are significant in connection with the observations frequently made as to the remarkably stimulating and restorative effects of Panopepton.

Why you should use

MARSHALL'S LYSOL

Because it is the original and the only lysol made to the formula and method used by the originators.

Every bottle has forty years of experience and bacteriological research behind it.

Control of the most rigid order is exercised in its manufacture. The raw materials used, which are the finest obtainable, are not purchased in the open market, but are especially manufactured to our own specification.

Absolute freedom from alkalinity and the lowest possible percentage of inert matter are guaranteed.

Uniformity of quality is a feature of MARSHALL'S LYSOL; also it is non-caustic and harmless to the most delicate membranes and tissues when used as recommended.

Solubility and a clear solution (lasting at least 24 hours with cold water) are always obtainable with MARSHALL'S LYSOL, and it has a bland and emollient action which is of great value in Midwifery, Gynæcology, Feminine Hygiene, etc.

Every Doctor and every Nurse requires an antiseptic which is efficient and economical, and MARSHALL'S LYSOL is the antiseptic recognised as the standard by the majority of Hospitals throughout the whole world.

Smiler. fed on Cow & Gate

Dried Milk for Safety

At————deaths from diarrhoea and enteritis fell from 105 in 1923 to 67 in 1924, but rose to 109 in 1926. There was a fall in 1927 to 61, and a further fall in 1928 to 56. Professor ————M.O.H., writes: "Once more the relationship between these diseases and the sub-soil (four-foot) temperature, which used to be so constant, failed to re-appear. Among the most important factors in bringing about this amazing decline in mortality from these causes, I think we must place the wide substitution of dried milk for so-called fresh but highly contaminated milk————" Dr.————adds that until the methods of the farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, he is definitely of the opinion that liquid milk should be banished from the dietary of infants.

"Medical Officer,"
Jan. 4th, 1930.

This resumé shows clearly the advance made in medical opinion during the last few years. Figures such as these show conclusively that raw cows' milk—"Nature's food for the calf"—is unsafe and unsuitable for the human infant. Discrimination in the choice of a dried milk food is, however, essential.

The makers of Cow & Gate have for over a quarter of a century endeavoured by every means known to science to produce each year a better product, and in the light of this experience they postulate without fear of contradiction that there is a great gulf fixed between ordinary commercial dried milk and that specially prepared for infant feeding.

Some babies cannot digest full cream milk; they should be put on Cow & Gate Half Cream. (BLUE TIN)

EXPORT COW & GATE specially packed for Hot Climates. (YELLOW TIN)

GET COW & GATE CHOCOLATE MILK FOR THE MOTHER

©V

PUERPERAL SEPTICAEMIA

It is now generally recognised, and has been again recently stressed by gynaecologists, that the principal causative agent in Puerperal Septicaemia is the Streptococcus Haemolyticus.

It is an interesting and important fact that Monsol, which is well known to have a selective action on Gram-positive organisms, has a particularly selective action on the strain Haemolyticus among the Streptococci.

The following table showing the relative dilutions at which Monsol is effective illustrates this.

STRAINS OF STREPTOCOCCI

DESIGNATION OF STRAIN	*SOURCE*	*DILUTION OF MONSOL*
"Diphtheritic"	Throat	1-100
Salivarius. Barnes 445	Mouth-Tonsillitis	1-100
Erysipelatis. 226	Lesion	1-150
Enterococcus Tissier 775	Faeces	1-150
Urine 8213	Urine	1-150
Rheumaticus. Beattie	Joint	1-300
Sputum A	Unresolved pneumonia	1-700
Sputum B	Unresolved pneumonia	1-700
Viridans 1080	Tonsil	1-1000
HAEMOLYTICUS 2060	—	*1-1500*
HAEMOLYTICUS B.C. 1498	—	*1-1500*
Mastitidis 2470	Mastitis	1-1500
Scarlatinae. Sherman 1892	Scarlet Fever	1-1500

The use of Monsol in obstetrics is, therefore, specially indicated owing to its selective germicidal power; while its non-irritant action on the most delicate mucous membranes and tissues, renders possible its use at dilutions far stronger than are germicidally necessary.

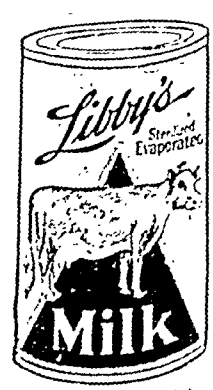
MILK



made more readily digestible.....*The Safe Wholesome Food for Babies.*

Libby's Evaporated Milk may safely be prescribed for infants because of the definitely known scientific facts that recommend it. It is always absolutely free from any germ or bacterial life, and is as easily digested by the infant as is mother's milk. By the process of homogenization all the solids of the milk are retained in perfect emulsion; the fat cannot separate. Sterilization in the sealed container keeps Libby's Evaporated Milk fresh and sweet. Furthermore, all the vitamins that milk can be depended upon to supply are present, and orange and tomato juice may be used with it as with any other milk.

The whole day's feeding can be prepared at once and will keep fresh and sweet.

Libby's Evaporated **Milk**

£1,000 *will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.*

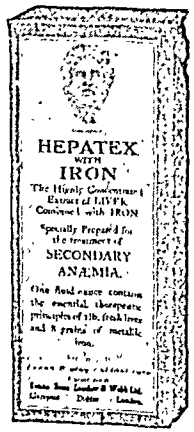
IZAL IN MIDWIFERY



HEPATEX (*Aesculapius*) **WITH IRON**

TREATMENT OF

Severe Secondary Anæmias

For the treatment of the severe secondary anæmias the use of liver in itself is of inconstant value. Likewise the administration of iron, while undoubtedly beneficial, does not always ensure that degree of improvement which is desirable. Liver and iron combined, however, have proved most effective.

HEPATEX WITH IRON provides a rational treatment for severe secondary anæmias. One drachm contains the essential therapeutic principles of 2 ozs. liver and 1 grain of iron. This iron, compared with ordinary iron preparations, is greatly superior as regards assimilation and absence of gastro-intestinal disturbances.

Issued in 2-oz. bottles, 7/6 each.

Gr. 5, bottles of 25 and 100, 7d. and 1/6 each

'TABLOID' PARATHYROID GLAND

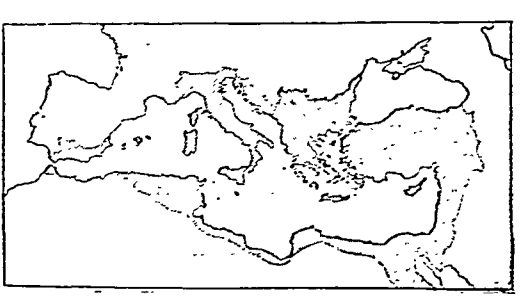
Gr. 2/5—equivalent to gr. 1/10 desiccated gland

Contains the genuine parathyroid gland

Bottles of 25 and 100, 3/4 and 11/8 each

'TABLOID' PARATHYROID GLAND AND CALCIUM LACTATE

Contains Parathyroid Gland, gr. 1/10, and Calcium Lactate, gr. 5



Bottles of 25 and 100, 1/8 and 5 5 each

Prices in London to the Medical Profession

MAP SHOWING THE EMPIRE BUILT UP BY THE BYZANTINES.—Constantine perceived that the situation and natural advantages of Byzantium rendered it an ideal defence against the peril from the Goths on the Danube and the Persians in Asia; moreover, it commanded the Black Sea trade. The Byzantine empire was built up from this centre. At the end of the fifth century it included the entire Balkan Peninsula (excepting the north-west portion), Asia Minor as far as the mountains of Armenia, Syria to beyond the Euphrates, Egypt and Cyrenaica. During the sixth century it was extended to its greatest proportions, as shown on the accompanying map. Many elements contributed to the population of Byzantine Constantinople; a Greek colony, which had existed there for many centuries, formed its nucleus, and to this were added large numbers of Romans who accompanied Constantine. Immigrants poured in from neighbouring lands, together with many Jews. Byzantine, scintillating with wealth and luxury, could absorb, amuse and employ them all. There gradually evolved a civilisation based essentially in the Hellenistic, but modified by a strong Oriental influence. Despite its derivative character, however, Byzantine civilisation did not lack a distinctive quality of its own.

Medinal TRADE MARK

THE ROUTINE HYPNOTIC.

Quickly absorbed.
Rapidly eliminated.

Clinical reports refer to its effectiveness in

INSOMNIA OF SENILE HEART, WHOOPING COUGH,

and particularly of

PNEUMONIA.

DOSE: 5-10 grains.

Veramon TRADE MARK

THE SAFE ANALGESIC.

Rapid in effect.
Persistent in action.

Of pronounced value in all varieties of pain from

SIMPLE HEADACHE TO INOPERABLE CARCINOMA.

Especially indicated in

DYSMENORRHŒA.

DOSE: 6-12 grains.

Clinical sample and literature on request from—

SCHERING LTD., 3, Lloyd's Avenue, London, E.C.3

Or from the following Overseas Depôts:.

CANADA— Schering (Canada) Ltd., P.O B 359, Montreal.
CEYLON— Paul Winn & Co. (Ceylon), Ltd., Colombo.
BRITISH INDIA— Schering-Kahlbaum (India) Ltd., P.O.B. 2006, Calcutta.
AUSTRALIA— Willmott Prisk & Co., Ltd., Sydney.

A British Medical Association Lecture

ON

PREDESTINATION IN DISEASE.

DELIVERED BEFORE THE WIGAN DIVISION ON DECEMBER 13TH, 1929,

BY

W. LANGDON BROWN, M.A., M.D.CANTAB., F.R.C.P.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE word "predestination" brings the grim figure of Calvin before the mind. But it is not with the theological aspects that I wish to deal. The flames of hell have lost their terror, but as man must be frightened about something, he terrifies himself about germs or cancer or whether he is eating enough vitamins. This fills the void, which disbelief in hell has left, quite satisfactorily. True, the scientific doctrine of determinism approximates to predestination. On that view every act is predetermined by our reaction to some afferent impulse—determined by our original make-up as modified by the effect of previous impulses. This doctrine has been carried to its logical conclusion by Freud when he maintains that slips of the tongue or pen and forgetfulness are the result of causes which can be discovered and which throw light on the working of the unconscious level of our minds. On this view the only variable factor in a man's behaviour comes from his environment, which may vary the kind of stimulus he receives—the rest is predestined.

Now I would like to say, in passing, that while I object to the doctrine of the verbal inspiration of Freud, and while I think he bases his views of the origin of the instincts too much on one instinct, I do really feel that when the dust of controversy has cleared away Freud will be recognized as one of the most original thinkers of our time, and his scientific achievement equal to that of Darwin. But I do not intend to-night to delve into the mysteries of the unconscious. Mine is a less ambitious task—that of estimating the effect that modern work has had on the doctrine of diatheses.

DIATHESES.

Even in the days of Hippocrates the doctrine of diatheses was taught, and it survived into the latter half of the nineteenth century. What exactly is meant by diatheses? Jonathan Hutchinson, in his lectures on "The pedigree of disease," in 1884, defined a diathesis as any bodily condition, however induced, in virtue of which the individual is, for a long period, or usually through the whole life, prone to suffer from some peculiar type of disease. Some diatheses, he said, are inherited, others are acquired. Of some the effects are permanent or constant, of others they are transitory, or recurrent after intervals of health. Later on, in the same course of lectures, he defined diathesis more briefly as "any condition of prolonged peculiarity of health giving proclivity to definite forms of disease."

But the bacteriological conception of disease that had been initiated by Pasteur had already thrown the doctrine of diatheses under a cloud. The scrofulous diathesis was a conception which was particularly open to attack. Not only were some observers confusing syphilitic with tuberculous diseases under that heading, but even those who were free from this gross error did not sufficiently distinguish between the tendency to infection by tubercle and a condition in which such infection had already occurred. It may be said that both syphilis and tubercle are infective granulomata, but it must certainly be admitted that a definition which does not draw a clear distinction between them is really worthless. Moreover, the strumous diathesis was open to a similar criticism, that it did not distinguish between the liability to, and infection by, tubercle. Nothing much can be said in favour of a classification which confused some cases of glandular tubercle with syphilis and attempted to separate others into two different diatheses. Yet, curiously enough, it was exactly the same point which, after helping to overthrow the doctrine of diathesis, then helped to dethrone the bacteriological factor from its supremacy. When it was realized how ever-present the tubercle bacillus was, how exposed everyone was to its inroads, and how comparatively few submitted to those inroads, it was forced upon our attention that the seed was not all-important, the soil must also be considered. Fortunately that seed falls upon stony ground in most of us. And so back came diatheses, with a difference. A new interest was awakened in the subject of natural immunity.

But despite Jonathan Hutchinson's gallant attempt to stem it, the tide was to run strongly against diatheses for some years to come. Nor is this surprising if we read those lectures. Surely never was the saying that the wisdom of one generation is the foolishness of the next better illustrated. Here was a man of unique clinical insight, extraordinary powers of observation, and great experience, making inevitable mistakes which would not be tolerated to-day in a candidate for his diploma—inevitable because he had not the data on which to base a correct opinion. Who to-day would dare to speak of the malarial diathesis, or who would attribute leprosy to the eating of unwholesome fish? Yet mingled with these errors are numerous shrewd guesses at future developments. Thus he quotes Spencer Watson as saying, in 1882, that "free exposure to sunlight and warmth would do much to enable a child improperly fed to effect assimilation in such a way as to keep clear of rickets." And he concludes thus: "We may certainly believe it probable that our climate and the narrow, sunless streets of our large towns take their share in the production of rickets." Yet it was not until after the war that this view was set on a sound scientific basis. We shall be very lucky if, forty-five years hence, our theories and conclusions of to-day stand the test of time as well as those of Jonathan Hutchinson.

When I entered St. Bartholomew's Hospital in 1894, only one of my teachers referred to diatheses without an apologetic smile. Sir Dyce Duckworth alone maintained a robust faith in them. Yet at that very time Weismann, the Calvin of biology, was laying down the rigid doctrine of the germ plasm. No acquired character was transmitted, he averred, for acquired characters only affected the somatic cells, and in the germ plasm alone did heredity reside. Later on the discovery of the chromosomes and the rediscovery of Mendel's work seemed to place this doctrine on an assured basis. This inevitably brought the idea of predestination into medicine. The progress of human thought is always in a spiral; the turn of the spiral had now been reached, and, as I have already said, back came diatheses, with a difference.

It is interesting to see how, even in some matters of detail, the old ideas have been coming back. In 1852 Dr. Laycock published his lectures on "Physiognomical diagnosis," in which he called attention to certain facial types which assisted in the diagnosis of the diseases from which their owners were suffering; and Draper at Columbia University is at present studying this subject anthropometrically, and trying to establish by direct measurements the existence of certain types, such as the gall-stone type, the peptic ulcer type, and the pernicious anaemia type. He has collected a mass of data in his book *Human Constitution*, and has certainly revived an interest in the subject of diathesis. I have had the pleasure of his company in my wards at St. Bartholomew's Hospital, and it was clear that his system enabled him to make shrewd and often correct guesses at the diagnosis, though I think he will have to do far more work before his conclusions command wide acceptance.

My main purpose is to discuss certain recent investigations which give us some hopes that we are arriving at clearer views as to the factors which go to determine liability to disease, factors which admit of some accuracy of determination, some degree of measurement. I refer to such subjects as inborn errors of metabolism, idiosyncrasy, endocrine balance, and the posture of the viscera. I will deal first with those which express themselves through some recognizable chemical disturbance.

Inborn Errors of Metabolism.

This term was introduced by Sir Archibald Garrod to describe certain congenital abnormalities which could be diagnosed by chemical tests. They are so rare that a man may spend his whole professional life in busy practice and never see a case. They may lead to a disease in some instances, but they more frequently cause no discomfort. It might be thought, therefore, that their study is a wasted endeavour. But by years of careful observation Sir Archibald Garrod was able to arrive at certain general conclusions which have thrown much light on the way in which the body works, and on some important factors in our constitutional make-up.

The inborn errors which are at present recognized are albinism, alkaptonuria, cystinuria, pentosuria, and porphyrinuria. Four out of the five, therefore, are characterized by the presence of an abnormal substance in the urine. But each of these substances, though not normally excreted, is a normal intermediate product of metabolism. The peculiar feature, then, is that in persons suffering from such conditions the ordinary breaking down of their tissue cells stops short at a certain point, and the product formed at that stage is excreted. In the remaining example, albinism, there is evidently a closely similar state of affairs. The albino is unable to manufacture any pigment containing melanin, and if he is given melanin he merely excretes it as such, although he can manufacture the pigments of blood and bile just like an ordinary man.

Now we have been gradually forced to recognize that each successive step in the building up or breaking down of all tissue components, even of individual fractions of proteins and of individual sugars, is the work of special enzymes or ferments set apart for each particular purpose; and, to quote Garrod: "If any one step in the process fail, the intermediate product in being at the moment of arrest will escape further change, just as when the film of a cinema is brought to a standstill the moving figures are left, foot in air." Very curious, you may say, but not important, considering the rarity of these conditions. But wait a moment; Garrod quotes a far-seeing remark which Claude Bernard made in 1880: "Would anyone dare to maintain that it is necessary to distinguish the laws of life in a pathological state from those laws in a normal state? That would be like distinguishing between the laws of mechanics in a house that falls down and in a house that remains standing." In other words, the great value of the study of these inborn errors of metabolism is that they have shown us some of the intermediate steps taken in the ordinary metabolism of tissues and have helped to prove that each step requires its own special ferment.

These inborn errors of function are the chemical analogues of structural malformations; they do not tend to get worse, but they may predispose to further trouble. The alkaptonuric passes a urine which darkens on standing and reduces Fehling's solution, thus perhaps leading to an erroneous diagnosis of, and unnecessary treatment for, diabetes. But he may also develop a special form of arthritis and be inconvenienced by ochronosis, a pigmentation of his conjunctivae and of his cartilages similar to that which may be developed by prolonged use of carbolic acid—for example, as a dressing—and essentially due to a similar chemical cause. The cystinuric has no inconvenience unless he contract an infection of his urine, when he may develop a cystin stone in his kidney or bladder. The pentosuric is unable to deal with the special sugar which is set free in the breakdown of the nucleo-proteins of his cell nuclei, but will suffer from no inconvenience unless he tries to insure his life, when he is very likely to be unnecessarily rejected. As for the porphyrinuric, we know that the haematoporphyrin of the blood pigment is a sensitizer to light. If haematoporphyrin is injected into each of two albino rabbits and one is kept in the dark no harm will result to it, but if the other is allowed to run about in sunlight it will die. It has no protective pigment, and the free haematoporphyrin makes it fatally sensitive to light rays. Haematoporphyrin in the combined state enables actinic rays to reach the hidden recesses of our body through the blood stream, but the individual who is unable to decompose it when red blood corpuscles die a natural death is so sensitive to light that every summer he is apt to develop a vesicular rash on any exposed part.

Such errors of metabolism fulfil Jonathan Hutchinson's definition of a diathesis—"any condition of prolonged peculiarity of health giving proclivity to definite forms of disease." A further point of great interest is that these inborn errors of metabolism are liable to occur in several members of the same family, most often in collaterals of the same generation, born of normal parents. Direct transmission from either parent to child is very rare. Like many such abnormalities, they are specially liable to occur in the offspring of marriages between first cousins. Much has been said against such marriages, but it is generally admitted to-day that the mere fact of consanguinity of parents cannot cause "an anomaly to appear *de novo* in their children, but it is obvious that the reappearance of a latent character which both parents tend to transmit is likely to be favoured by the mating of members of certain families" (Garrod). What is often forgotten by opponents of such marriages is that favourable variations are just as likely to reappear as unfavourable ones. Hereditary genius has apparently been fostered by the marriage of first cousins. Of course, if such intermarriages were frequently repeated in a family, the ordinary bad effects of prolonged inbreeding would assert themselves.

The proportion of first-cousin marriages in this country is estimated at between 3 to 5 per cent. of all marriages, yet of 34 cases of alkaptonuria 15 were in the children of first cousins—that is to say, 44 per cent. of the cases sprang from marriages which constitute less than 5 per cent. of the total marriages. The late Professor Bateson pointed out that the mode of incidence of alkaptonuria finds a ready explanation if the anomaly in question be regarded as a rare recessive character in the Mendelian sense. Naturally such recessive characters are more likely to occur when the parents are consanguineous.

I have dwelt at some length on this rare group because of the light they throw on questions of wider interest. They show that each step in metabolism requires its special ferment, that the absence of some special ferment may induce a predisposition to a disease, and that this lack may be transmitted according to the Mendelian laws of heredity. Such clear-cut results in this narrow field will doubtless find applications in wider fields. In gout we have an error of metabolism, which is sometimes clearly inherited, but sometimes apparently acquired. Yet that apparent acquisition may perhaps only be a latent inborn tendency made active by habit or environment. The chemical factor is an inability to deal with the uric acid set free by the breakdown of nucleo-proteins, yet it often requires the presence of a low-grade sepsis to make it effectively noxious. Routine analyses of the blood have shown that many more people have excess of uric acid there than have ever had gout. Of all hereditary diseases haemophilia is the most striking, both because of its dramatic and often tragic manifestations, and because, as a corollary of this, of the detailed knowledge we have of its method of transmission. Cases have been traced back in an exalted family as far as 1500; Dr. Drury mentions a family in South Africa, springing from old Dutch settlers, in which haemophilia has been traced back for twelve generations, over a period of 250 years and affecting 610 individuals.

In every case the method of transmission is the same—by the female line, though only males are affected. This gives us some clear evidence to go upon, for sex is a Mendelian characteristic, dependent on a chromosome. Females have an even number of chromosomes, males have an odd number, being one short. This odd one is called the X chromosome, but some sperm cells contain this, others do not. The union of an egg cell with a sperm cell containing an X will result in the offspring being a female, while such union with a sperm cell which does not contain an X mean; that an unpaired X will result, and the offspring will be male. It would therefore appear that haemophilia is due to the transmission of an X chromosome derived from the egg cell which has remained unpaired at fertilization. If it is paired this peculiar chromosome is rendered harmless. We know that in certain

animals particular characters are transmitted by particular chromosomes, but this, as far as I know, is the only instance in which we can apparently associate the transmission of a disease in man with one recognizable chromosome. But, further, we know that the haemorrhagic tendency to haemophilia, unlike purpura, is due to a delay in the coagulation time, and that this delay is due to a lack of one of the constituents of the fibrin ferment—namely, thrombogen. Here, therefore, we have a deadly disease due to the lack of a particular ferment which is transmitted according to definite Mendelian laws. In other words, it fulfils the same criteria as those demanded by the rare and seldom serious inborn errors of metabolism.

The transmission of the pseudo-hypertrophic form of muscular dystrophy is similar—that is, it is transmitted by the female line but usually attacks males. However, girls occasionally suffer from the disease, though it is five times more common in boys than in girls, but this is sufficient to destroy any idea of its necessary connexion with the X chromosome. Spiller's remark in Osler and McCrae's *System of Medicine*, that "it seems extraordinary that sex should influence the onset of this disease, especially at so early an age," ignores the fact that sex is dependent on the chromosomes, and is determined at the moment of fertilization.

Another rare familial disease which has some interesting bearings on my topic is familial haemorrhagic nephritis, of which I have seen examples in two different families. The most striking group is the family described by Hurst, of which I saw two members. In this family there were 27 persons in three generations, of whom 16 suffered from nephritis. The males were much the most seriously affected, all the affected ones having succumbed with the exception of one child in the third generation, while the females were involved to a much lesser degree, and only two succumbed. In the early stages there was merely haematuria, and Leonard Guthrie, who studied some of the earlier cases, preferred not to label them as nephritis; but later on undoubted nephritis developed, and typical uraemia has closed the scene in several. In the two patients I had the opportunity of seeing, the passage from haematuria to nephritis was distinctly observed in the boy, but not in the girl. Dr. Hurtley kindly made some biochemical tests, and we found it possible to predict the onset of the haemorrhage by noting an increased concentration of the urine and an increased output of neutral sulphur. This suggested to us that some abnormal protein breakdown was the immediate cause of the haemorrhage, and that repeated irritation of the kidney in this way led to nephritis. It is an interesting fact that in some members of the family certain articles of diet, especially black currants or claret, would induce an attack. I strongly suspect, therefore, that the nephritis in this family was the consequence of some error in metabolism which resulted in the excretion of intermediate products in a form damaging to the kidney. This has an interesting bearing on Aschoff's views as to the importance of a pre-renal factor in inducing nephritis, while bringing the familial type into close relationship with the other errors of metabolism I have mentioned.

Idiosyncrasy.

I next come to the subject of idiosyncrasy as a factor in predestination in disease. Sir Humphry Rolleston considers that idiosyncrasy is a semi-popular rather than a scientific term, but briefly defines it as an unusual physiological equation. It is a special instance of allergy, a term introduced by von Pirquet to describe all forms of altered reactivity of the organism. It therefore includes hypersensitiveness on the positive side and immunity on the negative side, but is now commonly confined to the former condition. Very often allergy is restricted to an inborn sensitiveness, while the term "anaphylaxis" is applied to an acquired sensitiveness. Here we are only concerned with an inborn sensitiveness. Morley Roberts has made the profound remark that "immunity is assimilation." There is one flesh of birds and another of beasts. From the welter of amino-acids which result from the disintegration of food proteins each animal has to build up its own characteristic and specific tissues. Specificity is chemical as well as morphological. To some foreign proteins we are naturally immune—that is, we can assimilate them automatically; to others we acquire immunity—that is, we learn to assimilate them; but to some foreign proteins immunity is neither congenital nor acquired. The tissues continue to resent the intrusion of such. They will not assimilate them. Such proteins excite anaphylaxis, or, more strictly, allergy, in varying degrees. Richet has defined anaphylaxis as the last stand of the race against adulteration of its protoplasm. In extreme degrees anaphylactic shock is fatal because assimilation would mean too profound an alteration of bodily structure. In less degrees both allergy and anaphylaxis declare themselves in violent attempts to get rid of the foreign invader. These attempts take the form of diarrhoea and vomiting, of giant urticaria, or of asthma. Hypersensitiveness, then, is the refusal on the part of the individual's protoplasm to attempt to deal with certain foods and drugs in order to conserve its own identity. If inborn errors of metabolism indicate a difficulty in katabolism, idiosyncrasy indicates a difficulty in anabolism. It gives a scientific basis for the old saying that one man's meat is another man's poison. The substances which excite these reactions are not in the least toxic to the ordinary individual. Freeman has injected himself intravenously with doses which would be fatal to a sensitive subject without any symptoms resulting. He has given rabbits enormous doses of an extract of grass pollen, such as would kill a pollen-sensitive asthmatic, without any results. Indeed, one can hardly imagine a rabbit being sensitive to grass pollen. Such rabbits could not survive in the struggle for existence.

Some years ago I saw an extreme example of hypersensitiveness to eggs in a young man. He was made very ill by the minutest trace of egg-white, whether he was conscious of taking egg or not. He did not know that a roll might be glazed by egg-white until it produced the following distressing symptoms—an immediate tingling sensation on the tongue, followed by a shudder; then copious salivation, first frothy, then in long viscid strings, difficult to spit up; next, spasmodic contractions in the throat, rendering it most difficult to swallow even saliva; then severe abdominal pains and cramps, continuing for about eight hours. A larger quantity of anything containing egg albumen would cause violent diarrhoea and vomiting, with alarming collapse. I have noted that egg-sensitive persons are liable to be upset by eating chicken, and it is well known that if one emanation from an animal causes a reaction others from that animal will do likewise. The man who gets asthma from horse dandruff will get a violent rash and joint swellings from an injection of horse serum, and may have an alarming and even fatal collapse. On this fact the protein skin tests have been based, and it has been claimed that in this way the peccant protein may be discovered. Unfortunately this method has not proved the success in practice that was anticipated. The patient may show a reaction to a large group of substances, and is not constantly sensitive to the same substance. Thus I saw a patient who was emaciated and profoundly depressed, but whose chief objective trouble was a painful swelling of the tongue and lips. His skin reactions showed that he was highly sensitive to cereals, which were accordingly removed from his diet, and he made a dramatic improvement, gaining 16 lb. in weight in one month. Later on he relapsed, and a repetition of the skin tests showed that, although he was no longer sensitive to cereals, he gave a marked reaction for some other groups.

Intradermal tests are the best, and the Schick test for diphtheria and the Dick test for scarlet fever, which are based on that method, have proved of great value in distinguishing between those who are naturally immune to and those who are susceptible to these diseases.

Briefly to summarize this section—immunity and hypersensitivity are the opposite poles in an assimilative process; if the cell can assimilate a substance it is immune to any toxic results that substance might produce; if it is hypersensitive to that substance this is because it cannot assimilate it. From the make-up of their protoplasm some individuals are quite unable to do this, and are therefore predestined to suffer if exposed to material which for them may be highly toxic.

The Sympathetic-Endocrine Balance.

Time will not allow of my making more than a brief reference to the important factor of the endocrine balance. That some individuals inherit an imperfect equipment of endocrines is well recognized; a family tendency to thyroid disturbance is frequently seen—and, curiously enough, the balance may lead to overaction in one member and to underaction in another of the same family. Now there is a very interesting point in connexion with Graves's disease. It is always accompanied by a persistent and usually enlarged thymus. The thymus should have atrophied before puberty; it is an infantile gland which retards the development of sexual maturity. On the other hand, Graves's disease seldom develops before puberty, so that it would appear that only those patients in whom the thymus fails to atrophy are capable of developing Graves's disease. Here, therefore, we have again a family liability to a disease, in this case associated with the persistence of an infantile gland. Cases of hypopituitarism also tend to run in families. As for pluriglandular syndromes, these are, in my experience, usually associated with a gonadal defect, which naturally interferes with fertility. In this way a family in which the endocrine balance is too grossly disturbed tends to die out. Mott has shown that exactly the same thing happens in some families liable to mental disease. The mental trouble tends to occur earlier and earlier in each generation until, by producing dementia praecox, in which there is usually gonadal deficiency, the propagation of this inherited defect is checked. It is to be regretted that this method of eliminating mental disease is not more widely adopted by nature.

We know that the endocrine glands, the thyroid, adrenals, and pituitary, co-operate with the sympathetic nervous system, while the pancreas, and possibly the parathyroids, co-operate with the vagus. Eppinger and Hess have tried to classify the neurotics into two main groups—the sympathicotonics and the vagotonics. While not accepting all their conclusions, which are certainly too hard and fast, we may agree that there is a group whose tendency to an overactive sympathetic is displayed by tachycardia, overaction of the thyroid, adrenals, and pituitary, a tendency to high blood pressure, a raised blood sugar, and a liability to glycosuria. Such individuals easily develop a temperature from a trivial infection. Temperamentally they are liable to phobias. On the other hand, we have the type where the overacting vagus displays itself by a slow pulse, liability to syncope, asthma, hay fever, urticaria, spastic constipation, and low blood sugar. They react badly to infections, and their temperament is one of vague apprehension. Such patients are often a good deal benefited by belladonna, which paralyses the vagal endings. I have referred to the chemical idiosyncrasies of the asthmatic, but he is also the victim of this overacting vagus. But this overaction may be relative rather than absolute; I mean that an underacting sympathetic may tip the balance in the direction of the vagus. Thus Widal reported the case of an asthmatic who subsequently developed myxoedema; treatment by thyroid extract not only relieved the myxoedema but also the asthma. Indeed, the relief of the asthmatic paroxysm by injections of adrenaline is another example of restoring the balance in favour of the sympathetic. These tendencies to a disturbance of the balance in one direction or another certainly run in families, and Cammidge has collected family histories which suggest that their inheritance follows Mendelian laws.

Achlorhydria.

I wish specially to call your attention to the way in which the absence of hydrochloric acid in the gastric juice may predispose to various diseases. In many respects we do not attach the same importance to gastric digestion as formerly. A man can assimilate his food after a total gastrectomy, and the pancreas is not so dependent on gastric HCl to start its secretion as Bayer and Starling concluded. But in one respect the HCl is now known to be of greater importance than was suspected, and that is in its bactericidal action. Indeed, as I pointed out a good many years ago, it may well be that the reflex hyperchlorhydria excited by some infection lower down in the alimentary tract is an attempt to check further bacterial invasion from the mouth. Now achlorhydria may be acquired as the result of prolonged chronic gastritis, but it may also apparently be congenital. Indeed, according to Izod Bennett, it is just about as common as red hair. Bennett and Ryle in 1921 found by fractional test meals on 100 healthy medical students at Guy's Hospital, that 5 per cent. had complete achlorhydria, while 15 per cent. had hyperchlorhydria, the remaining 80 per cent. having normal curves. Now it is a well-known fact that certain diseases are always associated with achlorhydria, whether congenital or acquired, while certain other diseases are more likely to occur in its presence. Let me take, as the most striking instance, *pernicious anaemia*. When Dr. William Hunter, some thirty years ago, called attention to the association between pernicious anaemia and oral sepsis, one wondered why the disease was not far more common, considering how little attention was then paid to oral hygiene. Then it became clear that it never occurred unless achlorhydria was also present. Other sufferers from pyorrhoea might suffer from many diseases, but never from pernicious anaemia. I have seen pernicious anaemia develop in achlorhydria that has been acquired—for example, by short-circuiting—but that the achlorhydria which is responsible is usually congenital is suggested by this being an abnormality affecting 5 per cent. of the population, and is made almost certain by Hurst's observation of its more frequent occurrence in the families of patients with pernicious anaemia. The discovery of the efficacy of liver treatment in pernicious anaemia has given a new orientation to our outlook, but the primary importance of achlorhydria remains. Indeed, recent work by Castle of Boston helps to reinforce it. He showed that the normal products of the digestion of meat by gastric juice had much the same effect as liver. He concluded that this acid digest stimulated the patient's liver to produce something which prevented the breakdown of red corpuscles; the normal liver we administer contains that substance pre-formed.

Another disease which is invariably associated with achlorhydria is *subacute combined degeneration of the cord*. Collier, Batten, and Risien Russell, in 1900, showed that this disease might anticipate or follow pernicious anaemia, or occur independently. They concluded that it was due to the same toxin. Since then repeated fractional test meals have proved that it never occurs without achlorhydria, and it is also recognized that some degree of cord change is often found in pernicious anaemia, if it is carefully looked for. Once degeneration of the cord has occurred, treatment by liver is, of course, unable to restore it, but in the earlier stages, when there are only toxic symptoms and before structural changes have occurred, this remedy is of decided benefit. Curiously enough, this disease seems specially common in Newcastle, and although most neurologists would not accept the diagnosis in some of the cases reported there by Ungley and Suzman, two facts stand out—toxic symptoms resembling subacute combined degeneration of the cord were often relieved by liver treatment, and achlorhydria was common in the healthy members of the families of patients suffering from suspected or declared cord changes of this kind.

I have been greatly struck with the frequency of *achlorhydria in ulcerative colitis*, and with the great benefit which has been derived from the administration of HCl in these cases. I was led to this by Hurst's observation of the frequency of achlorhydria in various forms of irregular *diarrhoea*. In such cases I have generally found a normal intestinal flora on bacteriological examination of the stools, or at any rate the absence of any definitely pathogenic organism. This indicates a weakness of defence rather than of strength of attack. I saw a man in a severe attack which cleared up on HCl which he continued to take for eighteen months after recovery. Six months after giving it up he had an even more severe attack, from which he bled so seriously as nearly to lose his life. After transfusion and routine administration of HCl he slowly recovered again, and is now apparently well. But such a man should continue to take HCl for the rest of his life.

Hunter called attention to another feature of pernicious anaemia—namely, glossitis leading to a loss of papillae. Now this raw, sore tongue is found in certain other conditions, and it is gradually becoming recognized that these are generally, if not invariably, associated with achlorhydria.

Sprue was the first of these in which this triad of symptoms—anaemia, glossitis, and achlorhydria—was recognized, and, as we know, it is characterized by a general thinning of the mucosa of the alimentary tract and by diarrhoea. We all know the neurotic woman who, generally about the time of the climacteric, complains of a sore tongue. It might be suggested by a cynic that this is due to the habitually caustic use such patients make of that organ, for their bad temper is proverbial. They are the *despair of the general practitioner, for they are a mass of* phobias, and naturally particularly of cancerphobia. Now it is an interesting fact that many of these patients have achlorhydria, and some of them can be benefited more by HCl and parathyroid with calcium salts than by all the nerve sedatives inside or outside the Pharmacopoeia. Here we have the triad of achlorhydria, glossitis, and purely functional nervous symptoms.

Lately, however, a more definite syndrome has been recognized—achlorhydria, glossitis, anaemia, dysphagia, and sometimes an enlargement of the spleen. The anaemia is usually not of the *pernicious type, but is secondary in* character. I take it that the dysphagia, which is referred to the oesophagus, is due to a similar loss of mucous membrane lower down than the mouth. My colleague Dr. George Graham kindly allows me to mention a case, as yet unpublished, in which the dysphagia cleared up on liver extract, although here, too, the anaemia was not of the pernicious type.

Two other conditions remain to be mentioned in which achlorhydria *is very common. One is acne rosacea* and the other *rheumatoid arthritis*. Herein we get a therapeutic suggestion for two troublesome diseases. But by no means all cases of the latter have complete achlorhydria, though some reduction in the normal secretion of acid is very common. If a fractional test meal is normal in a case of rheumatoid arthritis, it suggests that the infective focus is below the duodenum, and it should direct our attention specially to the pelvic organs.

I believe that the real route of infection which achlorhydria permits is by way of the duodenum. Normally the duodenal contents should be sterile, but *duodenal* intubation will prove that in such cases marked infection is present.

We arrive, then, at the conclusion that there are certain diseases, such as pernicious anaemia and subacute combined degeneration of the cord, in which total absence of HCl is invariable, and others in which it is very common. Hurst even thinks that in *cancer of the stomach* achlorhydria exists before the new growth, and is not a result of the growth. Some years ago I saw a woman who wished for the fullest examination because her mother and daughter had died of cancer of the stomach. Nothing could be found but achlorhydria. Yet she, too, subsequently died of malignant disease of the stomach.

It is the 5 per cent. of the population who are congenital achlorhydrics that we may regard as having an inborn predisposition to certain grave diseases. The recognition of this state of affairs places in our hands a valuable therapeutic weapon, for since so many of these diseases can be relieved by a drachm of the dilute HCl of the *British Pharmacopoeia* in a glass of orangeade or lemonade at meals, it is highly probable that this treatment would have a valuable preventive action also. I would suggest that it is worth while for anyone whose near relation suffered from pernicious anaemia to have the acidity of his resting gastric juice estimated, and for him to take HCl as a routine if this is found to be *nil*. And I should like to bear testimony to the splendid and indefatigable efforts of Hurst and his fellow workers in emphasizing the great importance of this syndrome of achlorhydria, glossitis, and anaemia. To my mind it is one of the most helpful generalizations of recent years.

Next I wish to point out that the response of the stomach to various attacks upon it will differ according to certain peculiarities, possibly inherited, which are characteristic of the individual patient. Thus, as Barclay showed, the long thin subject tends to gastroptosis, while the short, stout type of man is more apt to show the hypertonic well-contracted stomach. For, as Sherrington puts it, there is a variation in the posture of the stomach by which the effect of gravity can be allowed for. But this may influence the type of dyspepsia he may develop in response to some stress or strain. If we may take Bennett and Ryle's figures as typical of the general population they will help to explain this fact.

Digestion starts in the mouth, and indigestion often starts there too. Apart from the bolting of food, and the tendency, if mastication is difficult, to take pappy carbohydrates, which without insalivation cannot be digested in the stomach, the constant swallowing of pus from *oral sepsis is now* well recognized as a fertile cause of dyspepsia. It may be considered that the typical effect of this is gastritis, by which I mean a diffuse inflammatory reaction of the mucous membrane of the stomach, resulting in an increased secretion of mucus and a masked secretion of HCl. I stress this because of the tendency to use the term "gastritis" in a very vague sense—a tendency much increased by the war, since gastritis was one of the few digestive diseases a soldier was allowed to have, by regulation.

One can readily understand that if a man is one of those who naturally have a low secretion of HCl oral sepsis is more likely to produce gastritis in him. On the other hand, C. H. Miller has shown that the starting-point of a gastric ulcer is generally a septic infection of a lymphoid follicle, while Bolton has shown that hyperacidity tends to keep such an ulcer from healing. Therefore, if a man is one of those who naturally have a high secretion of HCl oral sepsis is more likely to produce a peptic ulcer in him. Then, again, take the effect of alcohol. This typically also excites gastritis, and it is this special type of gastritis which is a necessary precursor of cirrhosis. If cirrhosis occurs it will produce portal congestion, and therefore more gastritis. Thus a vicious circle is set up. And if there is another cause for gastritis, like oral sepsis, present, the chances of his developing cirrhosis are increased, which explains why one man falls a victim to cirrhosis while his equally erring brother escapes. But if the too free imbiber of strong drink has a natural tendency to hyperchlorhydria and a hypertonic stomach, he is more likely to be rewarded with a duodenal ulcer than with cirrhosis; for, as Hurst pointed out, and as my experience would confirm, not only is the hypertonic stomach practically always present when there is a duodenal ulcer, it is there before ulceration occurs and after the ulcer is healed.

It would therefore appear that such mechanical and chemical idiosyncrasies as I have described will determine the type of digestive disease that will result if one of the exciting causes is present.

Yet one more example and I have done. The liability in certain families to early arterial degeneration is well known, and one special form of obliterative arteritis is known only to attack Jews. In Osler's phrase, it would appear that in some families *inferior* rubber is used in the tubing.

In conclusion, although I have ranged over a large, possibly too large, an area, I hope I have been able to give some idea of the more modern views on diathesis or proclivity to certain diseases. There are peculiarities of metabolism in some individuals which may take the form of a lack of some ferment or important secretion, or may display itself in an intolerance to the assimilation of substances to which the ordinary individual is immune. Some start out with an inadequate supply of endocrines or with a disturbance in the balance between the two great divisions of the visceral nervous system—the sympathetic and parasympathetic or extended vagus. The very posture of the viscera will modify the type of disease produced by similar causes. These predispositions to disease can be shown in many instances to be inherited according to Mendelian laws and to reside in the chromosomes of the nuclei of the gonads. It might be thought that they would be such a handicap in the struggle for existence that they would lead to their own disappearance by the destruction of the individuals possessing them. In some cases this is so, but we must remember that a defect which is not fatal to propagation will continue to be propagated—not perfection, but survival, is Nature's aim. But the importance of a knowledge of the family history is greatly enhanced by these recent observations, and for that knowledge we must depend on the general practitioner, who is, and must continue to be, the backbone of our profession.

UNDETECTED SYPHILIS AND RHEUMATIC INFECTION IN CHILDHOOD.*

BY

A. DINGWALL FORDYCE, M.D., F.R.C.P.ED.,

HONORARY PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

IN the course of work with rheumatic children I have recently been forced to consideration along new lines. Having had referred to me a child with acute rheumatism and carditis, it ultimately became evident that the rheumatic infection was superimposed upon a congenital syphilitic taint. Shortly afterwards a similar case was encountered, and I investigated a small series of cases with the object of obtaining information on the relationship between congenital syphilis and rheumatism. I obtained results which in their suggestiveness were to me striking and unexpected.

The following are the details, in short, of nine children dealt with in my rheumatic clinics, and who, I hold, were congenital syphilitics, and the striking feature in the cases is the frequent absence of clinical signs pointing to the presence of a syphilitic infection. I am impressed with the suggestion that an important subgroup of rheumatic children can be defined—namely, those in whom the rheumatic infection is superimposed upon congenital syphilitic infection, and more particularly untreated and undetected syphilis—and that prognosis in such cases may be seriously influenced.

The rheumatic child is not a clinical entity except in so far as the rheumatic infection is concerned, and it is possible to consider this infection in relation to the basic soil in which it acts, and to recognize that prognosis may be materially affected thereby.

When my interest was first keenly engaged in the consideration of the occurrence of rheumatic infection in congenital syphilitic children I searched my records for cases with unusual symptoms, or which had shown poor response to treatment, and carried out a Wassermann test on them. In this first group of cases there were 20 children, and to my surprise I was given a positive Wassermann reaction in 9 cases. Since then I have performed many Wassermann tests on rheumatic children coming to me for the first time, and usually the reactions have been negative. A few have been positive, but in this communication I deal only with my original group of 9 children, and the points that their examination appears to raise.

I wish to avoid laying any emphasis on the proportion of positive reactions in any series of cases, as I am dealing here with selected cases. I would also state that, as the result of many Wassermann tests on rheumatic cases, I have found no evidence that either in early or late conditions is the Wassermann reaction affected by the rheumatic infection itself.

The following is a brief synopsis of the 9 cases. I give these more fully later.

A.—*Evidence as to Rheumatic Infection.*

All the cases were sent to my rheumatic clinics by doctors, with a diagnosis of rheumatism.

In 5 instances (S. H., G. H., B. K., M. R., and F. P.) the children suffered from definite acute rheumatism and carditis while in hospital.

In 1 instance (M. M.) there was a history of rheumatic fever, and the child, when first seen, suffered from established valvular lesions (mitral and aortic).

In 1 instance (E. W.) there were various rheumatic symptoms, which were relieved by sodium salicylate. There were no cardiac signs.

In 2 instances (E. B., B. B.) there was a history of rheumatism; cardiac murmurs were present, but the exact significance of these was doubtful.

B.—*Evidence as to Congenital Syphilitic Infection.*

In 3 cases (E. W., E. B., B. K.) syphilis was admitted by the parent and the child's Wassermann reaction was positive. Of these 3 cases, in 2 instances there were no clinical signs of congenital syphilis.

In 1 case (S. H.) syphilis was denied by the parents and the Wassermann reaction of both parents was negative. The child, however, showed clinical evidence of congenital syphilis, and repeated Wassermann reactions were positive.

In 1 case (G. H.) the child showed clinical evidence of congenital syphilis and the Wassermann reaction was positive.

In 4 cases (F. P., B. B., M. R, M. M.) the children had no clinical signs of congenital syphilis, but the Wassermann reaction was positive.

In all these 9 children I concluded there was evidence both of syphilitic and of rheumatic infection, but *in 6 of the 9 cases there were no clinical signs of congenital syphilis.*

Training and experience are against the acceptance and direction for treatment of a laboratory reaction in the absence of clinical evidence, but the results in these cases show cause for hesitation, at least in regard to this matter of rheumatism and syphilis. If the syphilitic taint may be present in the absence of all discernible clinical signs pointing to infection, and if under such conditions it may yet cause the myocardium to be a point of weakness, it is obvious that, in the event of rheumatic infection occurring—however much it may be a pure coincidence—it must be important, both for prognosis and treatment, to recognize the position by any means at our disposal. A Wassermann report may be misleading owing to many technical causes, and sometimes repeated reports are contradictory or indefinite, and thus again one has to consider if there is a call for doing this test, or paying attention to it when done, if there are no clinical signs of congenital syphilis. In view of the cases I report I cannot but conclude that a Wassermann test should be made—if not in all serious rheumatic cases, certainly in cases displaying unusual symptoms or perplexing physical signs; and, further, that unless the reaction is definitely negative, antisyphilitic treatment should be combined with that of sodium salicylate. An accurate definition of what we are to understand by a diagnosis of acute or active rheumatic infection is still wanting, and nodules are rare in the Liverpool area.

With regard to 3 of the cases I report (B. B., E. W., E. B.) it may be held that the grounds for a diagnosis of rheumatic infection are insufficient. While I consider that most, if not all, paediatrists would agree with my diagnosis on examination of the children, I recognize that there is associated with such criticism another problem—namely, how frequently are there met with children who display no recognizable signs of congenital syphilis, who have a variety of rheumatic symptoms and cardiac signs responding in some degree to antirheumatic treatment, and who are nevertheless sufferers from congenital syphilis.

With regard to treatment, my experience is too limited to permit me to say anything further than that in those cases in which I have employed antisyphilitic treatment (S. H., B. K., G. H., M. R.) I have noted improvement, whether the child displayed recognizable clinical evidence of syphilis or not. Cowan and Rennie[1] have stated:

> "We have found a positive Wassermann reaction in patients who had had acute rheumatic fever, but the recognition of even a specific element in the case, and resultant specific treatment, will sometimes turn the balance in the right direction."

In this country, however, little emphasis has been laid either on the possible importance of clinically undetectable syphilis (or for that matter on its existence at all) or on the need for bearing syphilis in mind when dealing with rheumatic children.

The work of Warthin[2] within recent years has been very noteworthy in that he demonstrates as a common result of syphilitic infection diffuse myocardial degeneration—an interstitial myocarditis leading to fibrosis. Johannessen,[3] Gestiera,[4] Friedländer,[5] and other authors also stress the frequency of myocarditis in congenital syphilitics. But there is this very important point to be borne in mind—that it is sometimes, or often, unaccompanied by any clinical signs of congenital syphilis. Thus Friedländer writes:

> "I am especially desirous of emphasizing the point that in many cases syphilitic myocardial degeneration may be the only manifestation of congenital syphilis."

*The subject of a communication to the Southport Medical Society, January 8th, 1930.

As regards the place of syphilitic infection in producing gross endocardial and valvular lesions the position is even less clear, and in connexion with congenital infection little is known. Matusoff and White[6] state: "It does appear, however, from our study, that well-marked clinical evidence of such involvement is not common." There is ever present the doubtful factor of superadded rheumatic infection.

Warthin (loc. cit.) says: "In the younger individual latent syphilis of the heart probably predisposes to secondary bacterial endocarditis"; but McCulloch,[7] as the result of twelve years' supervision of 1,500 cases of congenital syphilis, says:

"We feel very strongly that children who have congenital syphilis and who live to be a year or more of age do not suffer from heart disease any more than any other normal group of children. Each syphilitic child receives from time to time a very careful physical examination, so that we are inclined to believe that we have not overlooked any heart disease in these children."

Even, however, when we accept McCulloch's observations we are dealing with children recognized as suffering from congenital syphilis, and presumably under treatment, whereas syphilitic myocarditis is apparently often unaccompanied by clinical signs of congenital syphilis, and may even show a negative Wassermann reaction (Friedländer). It may be that rheumatic infection is no more common among congenital syphilitics than among other children—we do not know. But it is possible that there are many children suffering from congenital syphilis who have no obvious signs or symptoms, who are not recognized, and who are not treated. When rheumatism does affect such a child the prognosis must be affected, and it is possible that many bad rheumatic hearts are based on congenital syphilis.

Whether the incidence of the double infection be great or small, recognition of such a subgroup of rheumatic children should help to a flank attack on this subject of surprising difficulty—the etiology of rheumatism. The recent valuable papers of Nabarro and MacDonald[8] and of Cronin Lowe[9] emphasize, I think, the need and value of flank attacks and the probing into rheumatic manifestations under varying but determined physical conditions.

CASE HISTORIES IN DETAIL.

CASE I.

S. H., male, born 1920. Parents alive and healthy. Family: daughter, now aged 19 years, alive and well; then a miscarriage; then patient; then premature twins who died. Patient was admitted to another hospital on November 15th, 1928, suffering from "subacute endocarditis following tonsillitis" after having been treated as an out-patient. His abdomen had been noticed to be large since he was 7 years old, and he had been languid for two years. His liver extended to the umbilicus and was tender, the spleen extended five inches below the costal margin, his voice was husky, and Wassermann reactions recorded on November 8th and December 1st, 1928, were both positive (+).

The Wassermann reaction of both parents was negative, that of the father being tested twice. The patient was treated with mercury and iodide, and the liver diminished rapidly in size. He suffered, however, from a progressive anaemia of secondary type, and on February 25th, 1929, the blood picture was: red blood cells 2,737,000 per c.mm., white cells 3,300, haemoglobin 64 per cent., polymorphs 64 per cent., large lymphocytes 14 per cent., small lymphocytes 18 per cent., transitionals 4 per cent.

During January and February, 1929, he suffered from tonsillitis, pyrexia, cardiac weakness with diffuse systolic murmur, and involvement of the base of the left lung. He was transferred to the Royal Liverpool Children's Hospital on March 22th, 1929. At this time the heart was not enlarged, there was systolic bruit in all areas, the liver was palpable one inch below the costal margin, and the spleen was very large and extended below the umbilicus. A radiogram of the lungs was negative. A report on the van den Bergh reaction on April 24th was: "Direct=negative, indirect=medium positive." An electro-cardiogram seemed normal; blood fragility normal, blood culture negative. A Wassermann reaction on April 27th was strongly positive (++). He was treated with mercury and given a course of injections with kharsulphan (5 injections=0.06 to 0.14 gram). The Wassermann reaction on August 29th was still strongly positive (++); the spleen remained very large, the liver was palpable, there were many subcutaneous haemorrhages, and there were dilated veins over the lower thorax and upper abdomen. The heart was not appreciably enlarged; there was a rough aortic systolic murmur. Blood pressure: systolic 120, diastolic 70.

He was given another course of treatment with kharsulphan, but on October 11th the Wassermann reaction was still strongly positive (++). At this time, however, he was greatly improved in his general health, and had returned to school. The spleen showed no reduction in size. He was given another course of kharsulphan and continued in fairly good general health. On December 2nd the spleen was still very large, blood platelets 310,000, red blood cells 5,100,000 per c.mm., white cells 5,200, haemoglobin 105 per cent. Heart not enlarged, ? systolic murmur in aortic area.

This child is a congenital syphilitic with distinct clinical signs. He has suffered while under observation from acute rheumatism. Antisyphilitic treatment has been markedly beneficial, but the hepatic and splenic conditions are unsatisfactory, and raise problems outside the scope of my present survey.

CASE II.

G. H., female, born 1923. Parents alive—mother asthmatic and with Wassermann reaction (December 5th, 1929) negative. Nine other children, all weakly.

The patient had jaundice when 3½ years old, followed by diphtheria and pneumonia. She was admitted to the Royal Liverpool Children's Hospital, Heswall, on July 10th, 1928, suffering from pericarditis. On admission there was pyrexia, cardiac dilatation, pericardial friction, and a basal systolic murmur. The liver was large, the spleen palpable, blood culture sterile; facies of congenital syphilis. On treatment with sodium salicylate the pericardial friction disappeared in a few days, but later recurred, with tachycardia, and double mitral bruits. An electrocardiogram on January 7th, 1929, showed slight left ventricular preponderance. During the latter part of January and the early part of February, 1929, the child suffered from acute pyrexial pericarditis, with pleurisy and involvement of the left lung. Tachycardia and anaemia were present, the liver remained large, and the spleen became larger. In the beginning of April treatment was commenced with mercury (grey powder), and at the same time she began to improve. On August 2nd the Wassermann reaction was strongly positive (++), and at this time she was in fairly good general health, with a diffuse cardiac systolic murmur. On September 24th treatment was begun with potassium iodide in addition to mercury, and on November 8th the Wassermann reaction was negative. At this latter date the child was well, but the heart was slightly enlarged, and in addition to a systolic bruit there was suspicion of a presystolic mitral bruit. The liver and spleen were still large.

This child has clinical evidence to support a positive Wassermann reaction. She has suffered from acute rheumatism and carditis.

CASE III.

B. K., female, born 1919. The father contracted syphilis during the war.

The child was well till 1924, when she had pneumonia, measles, and pertussis, and remained weakly thereafter. During 1927 she suffered from suppurating cervical glands, which were repeatedly dealt with surgically. In September, 1927, she was treated in a hospital for acute rheumatism and carditis, the heart was greatly enlarged, a double murmur was present at the mitral area, and the electro-cardiographic report was: "left ventricular preponderance, P–R interval rather long, but not sufficiently long to indicate partial heart-block." A radiogram of the lungs was reported to be suggestive of tubercle. There was no enlargement of liver or spleen. Early in 1928 further scraping operations were performed on her neck, and in September, 1928, she was admitted to the Royal Liverpool Children's Hospital, Heswall, with the reported condition: "endocarditis, chronic osteitis of left femur, hoarseness, large unhealed wounds on neck from gland operations." At this time there was tachycardia, the left border of the heart was 3½ inches from mid-sternum, mitral systolic and diastolic bruits were heard to angle of left scapula, the pulmonary second sound was greatly accentuated, the aortic second sound was soft, with a blowing diastolic murmur.

On two occasions the Wassermann reaction was strongly positive (++). During May, 1929, she was given four injections (0.06, 0.12, 0.24, and 0.3 gram) of sulfarsenol, and at the close her neck was healed, the hoarseness of voice greatly improved, the leg greatly improved, and the heart improved. On July 6th the Wassermann reaction was positive (+). Potassium iodide and mercury were continued by the mouth, and during July and August a further course of sulfarsenol was given (0.12, 0.18, 0.24, 0.3, and 0.36 gram), and at the close she was in greatly improved health, had put on weight, and the glands and leg were well. She still had a large heart, with double mitral bruits.

She continued well, and gained steadily in weight. On October 26th she was stated to be "very well"; the heart was still large,

and there was a rough systolic murmur present. The Wassermann reaction on November 5th was still positive. When seen on December 6th she had continued well, but the heart was still large, with a diffuse rough systolic bruit.

This child is certainly a congenital syphilitic who has suffered from acute rheumatic infection.

CASE IV.

M. R., female, born 1920. Father a soldier. Two other children older than patient are alive and well. Since birth of patient there have been two miscarriages. The patient was a premature child, and has always been frail and tiny. She has had measles, pertussis, and scarlet fever.

She was taken ill in the beginning of September, 1929, and was admitted to the Royal Liverpool Children's Hospital on September 14th with acute rheumatism and carditis. The heart was dilated, and there were present double murmurs, both at the mitral and at the aortic areas. The general rheumatic symptoms improved slowly under treatment with sodium salicylate, but the cardiac condition remained unsatisfactory and the myocardial tone did not improve.

A Wassermann reaction on October 10th was "positive (+)," and on October 17th grey powder administration (1 grain daily) was commenced. By October 28th the heart tone was much improved, and dilatation of the heart was less marked. Another Wassermann reaction, taken on November 9th, showed the report "negative, but lysis is slightly delayed in serum dilution of 1 in 5." On November 19th another Wassermann report was: "Wassermann test is negative, but lysis is delayed in the presence of the larger quantities of the patient's serum." By November 22nd the cardiac condition had further improved, and while there were still double murmurs present at the mitral area, at the aortic area there was only a systolic murmur. Blood pressure: systolic 115, diastolic 75.

On December 21st a Wassermann reaction of the mother's blood was negative.

This child certainly suffered from acute rheumatism and endocarditis. She showed no detectable signs of congenital syphilis, and the mother's blood Wassermann test was negative. Shortly after the commencement of the administration of small doses of grey powder she commenced to show signs of improvement, and the Wassermann reports as detailed above were more than suspicious.

The evidence in favour of congenital syphilis is slender, but by no other means do I find the facts more readily explicable.

CASE V.

F. P., male, born 1915. There are three other children in the family, and a baby, born before the patient, died at 3 months from a "poisoned navel." One child is three years older than the patient, and the other two are younger.

He was first seen on July 11th, 1927, and had previously been treated for ? tuberculous cervical glands and nervous debility. During summer, 1927, he had various abdominal symptoms, and he was admitted to the Royal Liverpool Children's Hospital, Heswall, on August 11th of that year. While there he had an attack of acute rheumatism with pericarditis, involvement of the base of the left lung, and the development of double mitral murmurs. An electro-cardiogram on October 31st, 1927, showed left ventricular preponderance. He improved slowly but steadily, returned to school, and on May 24th, 1928, there was no enlargement of the heart and only a basal systolic murmur. He was kept under supervision, and had minor variations in health. On August 29th, 1929, there was nothing specially to be noted in the heart except a rough basal systolic murmur. On this date a Wassermann reaction was done, and the report was "reaction strongly positive (++)." He continued well and at school, and received no special treatment. He showed no clinical signs of congenital syphilis, but suffered occasionally from diarrhoea. Systolic blood pressure 110. Wassermann reactions taken on November 28th and December 12th were both negative.

This child suffered from acute rheumatism and carditis while under observation in hospital. A Wassermann test was done because the manner of his progress after illness seemed unusual, the cardiac signs variable and contradictory, and an altogether satisfactory diagnosis of the cardiac condition difficult to arrive at. It may, however, be that the first—or positive—Wassermann report was due to some error in the test.

CASE VI.

M. M., female, born 1916. Father died of pneumonia. One sister died of rheumatism; three others alive and well.

She was first seen on December 19th, 1927, with a history of acute rheumatism three years previously and several periods in hospitals because of heart trouble. The heart was greatly enlarged, and there were double murmurs at both aortic and mitral areas. Institutional care was refused, and while attending the rheumatic clinic for occasional observation her condition has remained practically stationary. There were no clinical signs of congenital syphilis, but a Wassermann report on August 29th, 1929, was "strongly positive (++)."

CASE VII.

E. W., female, born 1914. Father died in an asylum of general paralysis. Mother had injections during pregnancy with patient, and is aware she had syphilis. Patient was treated as a baby with rashes and sores for congenital syphilis.

Patient was first seen on September 26th, 1929, with the complaint of rheumatism, fleeting erythematous rashes, pains round the joints, shortness of breath, and easily tired. There was no clinical sign of congenital syphilis, and there was no obvious cardiac disability. Blood pressure: systolic 130, diastolic 70. Wassermann reactions of both mother and patient were recorded on September 26th, and showed reactions strongly positive (++). She was treated with sodium salicylate and sodium bicarbonate, and the symptoms on October 17th were greatly relieved.

There is no doubt that this child is a congenital syphilitic, but she shows no definite clinical signs. She also shows no definite signs of rheumatic infection, but she has suffered from rheumatic symptoms, which were relieved by sodium salicylate.

CASE VIII.

E. B., female, born 1921. Mother has had ten children; the first three were premature and died; the fourth and fifth died shortly after birth; the sixth is living and well, aged 18; the seventh a miscarriage; the eighth was premature and died; the patient was the ninth, and the tenth is alive and weakly.

Patient was first seen on July 6th, 1929, with a history of faints, shortness of breath, lack of energy, rheumatism, flitting joint pains, and cardiac murmurs. There was a loud rough systolic murmur over the precordial area, loudest in the aortic area, the heart was enlarged, and there was considerable albuminuria, with pus and *B. coli* in the urine. The mitral first sound was slapping in character; an electro-cardiographic report showed "T" inverted III, otherwise normal. Pulse small, no tachycardia. The Wassermann reaction on August 30th was positive (+).

She was at first treated with sodium salicylate, and though somewhat relieved showed no marked improvement, and on admission to the Royal Liverpool Children's Hospital, Heswall, on October 4th, there were double murmurs apparently at both mitral and aortic areas. During October and the beginning of November she was given grey powder (1 grain daily), and had a course of injections with sulfarsenol (0.06 to 0.14 gram). On November 12th she was greatly improved, the heart was not appreciably enlarged, there was only an aortic systolic murmur, and the Wassermann report was negative.

This child, because of history, original Wassermann reaction, and response to treatment, appears to be a congenital syphilitic, but has no clinical signs of the condition. She has also had rheumatic symptoms, with accompanying development of cardiac murmurs.

CASE IX.

B. B., female, born 1916. Father died, aged 40, after three "strokes"—the first "when quite young." Mother has had "heart trouble" since rheumatic fever when aged 12 years. The eldest child is paralysed, there have been two miscarriages and two stillbirths, and three other children are said to be well.

She was first seen on August 29th, 1927, being sent by the doctor as "old rheumatic endocarditis with anginoid symptoms, cough, and dyspnoea on exertion." She gave also a history of flitting pains and joint swellings. The heart sounds were weak, there were no murmurs, and the heart was not definitely enlarged. Precordial pain was present.

She improved under treatment with rest and sodium salicylate, but at later periods suffered from recurrent rheumatic symptoms, painful joint swellings, breathlessness, and precordial pain. There were no clinical signs of congenital syphilis. A Wassermann reaction on September 4th, 1929, showed "reaction strongly positive (++)." She was given grey powder (1 grain daily), and on November 8th another Wassermann test proved positive (+). A course of injections was proposed, but this was refused, as she had recently improved so much.

This child had a suspicious history and symptoms with a positive Wassermann reaction, but she has no clinical signs of congenital syphilis.

SUMMARY.

1. A series of 9 cases is described of rheumatic infection in congenital syphilitic children; in 6 of the 9 cases there were no obvious signs of congenital syphilis.

2. It is suggested that *undetected* syphilis may in some ses form a basis for the serious course of rheumatic fection, and, further, that the study of rheumatism may aided by the grouping of rheumatic cases along non-eumatic lines.

THROAT INFECTIONS AS AN ETIOLOGICAL FACTOR IN PUERPERAL FEVER.

*WITH A REPORT OF TWENTY-FOUR CASES.**

BY

W. W. KING, M.B., F.R.C.S.ED.,

LECTURER IN GYNÆCOLOGY AND OBSTETRICS, SHEFFIELD UNIVERSITY; HONORARY SURGEON, JESSOP HOSPITAL FOR WOMEN, SHEFFIELD.

THERE are a number of possible causes of puerperal infection, and in bringing evidence in support of the theory that organisms can be conveyed from the throats of apparently healthy attendants to the patient's genital tract during labour, I do not thereby exclude other sources of infection.

Faulty antiseptic methods cannot be the sole cause of puerperal sepsis, because: (1) the rate has not fallen during the past twenty years, in spite of the almost universal use of antiseptics; (2) it occurs in cases of "born before arrival"; (3) it occurs most frequently in hospitals, in spite of the most elaborate care; (4) it occurs in the private practice of even the most careful doctors and midwives. We have therefore to look for other etiological causes which are not influenced by efficient antiseptic technique. Our quest is simplified if we confine ourselves to the study of haemolytic streptococcal infections, not only because this organism is the most important cause of puerperal fever, but also because of its special characteristics, which are invaluable in its identification.

An analysis of the cases of puerperal sepsis admitted to the recently established special block for puerperal fever in connexion with the Jessop Hospital shows that there is not, as has been supposed, a winter prevalence of puerperal infection. The same characteristics are shown by the number of admissions to the puerperal fever beds at the Monsall Hospital, Manchester[1] (Chart 1). On the other hand, there

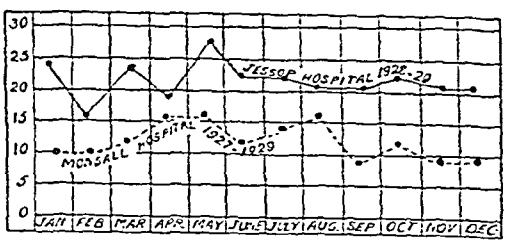

CHART 1.—Average monthly admissions of cases of puerperal sepsis, Jessop Hospital (1928-29) and Monsall Hospital (1927-29).

is a marked winter prevalence of puerperal infections caused by haemolytic streptococci, which in 1929 fell from 51 per cent. of the admissions to the Jessop Hospital in the first quarter to 14.5 per cent. in the summer quarter. This curve almost exactly corresponds with the latest available figures (1911 to 1924) of the average quarterly mortality from puerperal fever in England and Wales:[2] so that the type of infecting organism not only varies directly with the mortality from puerperal fever, but also with the time of the year when haemolytic streptococcal infections of the throat are known to be most prevalent (Chart 2).

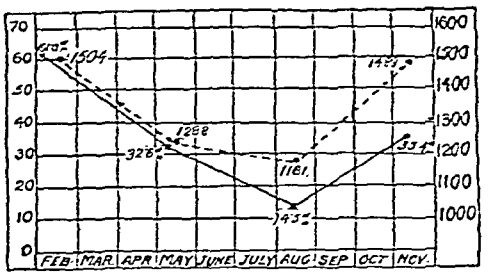

CHART 2.—Comparison between the average quarterly mortality (per million births England and Wales) from puerperal fever, 1911 to 1924, and cases of puerperal infection from haemolytic streptococci (per cent. of admissions of puerperal sepsis) to Jessop Hospital, 1929.

The following classified list (Table I) gives the causal organism which has been found in 236 cases of puerperal infection admitted to the Jessop Hospital last year. In

TABLE I.—*Type of Infecting Organism in the Genital Tract of 236 Cases of Puerperal Fever admitted to the Jessop Hospital.*

1929.	Total.	Haem. Strep.	Strep. viridans.	Strep.	B. coli.	Staph. albus.	Staph. aureus.	Various.
First quarter	59	35 (61.0 %)	2	6	2	2	2	9
Second quarter ...	65	15 (22.8 %)	6	5	11	13	1	10
Third quarter... ...	55	8 (14.5 %)	4	9	15	11	0	8
Fourth quarter ...	56	20 (35.6 %)	3	5	8	8	2	10
Totals	235	79	15	25	36	39	5	37

addition to the winter incidence of haemolytic streptococci, an interesting feature is the relatively high proportion of infections by *B. coli* in the summer, which may be related to the dry weather at that time.

Reference to the analysis of the type of labour (Table II) which preceded the onset of puerperal fever in the cases admitted to the Jessop Hospital in 1929 shows the surprising fact that those which had spontaneous labours had the highest rate of haemolytic streptococcal infections, while "failed forceps" cases, in which there is usually the maximum amount of manipulation and trauma, were only infected by haemolytic streptococci in 12.5 per cent. of the cases admitted.

TABLE II.—*Haemolytic Streptococcal Infections in Relation to Type of Delivery in 236 Cases admitted to Septic Block, Jessop Hospital (1929).*

	Total.	Infected by Haemolytic streptococci.
		Per cent.
Spontaneous deliveries (including "B.B.A.") ...	144	42.5
"B.B.A."	[92]	41.6
Operative deliveries (including failed forceps")	52	34.5
"Failed forceps"	[8]	12.5
Abortions	40	5.0
Total	236	

A most potent argument against the supposition that want of surgical cleanliness is really responsible for haemolytic streptococcal infections is found in the fact that this organism was present in only 5 per cent. of the septic

* From the Department of Obstetrics and Gynæcology, University of Sheffield.

abortions, most of which were criminal. It is not to be supposed that doctors and midwives are more septic than criminal abortionists. It is probable that the latter, while infecting their victims with every other type of organism, unconsciously protect them from haemolytic streptococci by carrying out their manipulations under the clothes, which at least form an efficient mask for the "operator's" throat.

The Endogenous Theory.

The possibility that the patient may harbour haemolytic streptococci in her vagina requires consideration. As a matter of fact, the theory, though logically possible, rather fails from want of evidence, because it has been shown (Bigger and FitzGibbon,[3] Lockhart,[4] Burt-White and Armstrong[5]) that haemolytic streptococci are rarely present in the vagina, and only then when the woman has been recently associated with a source of infection (Burt-White[6]). Burt-White and Armstrong found haemolytic streptococci only once in fifty-five cases (1.8 per cent.), and their results have been confirmed by a much larger investigation carried out in the ante-natal department of the Jessop Hospital by Dr. Pindar and Dr. Kirk.[7]

Bigger's[8] opinion that haemolytic streptococci are incapable of existing in the vagina as saprophytes which become pathogenic on reaching damaged tissue is supported by the figures given in Table II, which show that the cases with the greatest amount of trauma have the lowest percentage of haemolytic streptococcal infections. Thus, not only do the laboratory results agree, but they also coincide with the consensus of clinical opinion among obstetricians that, while prenatal vaginal infection is possible, it is not an etiological factor of high importance in the incidence of puerperal infection.

True autogenous infection, by which organisms pass to the genital tract from a focus of sepsis elsewhere in the body, must be a possible factor in the etiology of puerperal infection. In this series there is no conclusive example that the throat was such a focus. Among the fifteen patients who were examined, only one throat (Case 1) was found to be infected by haemolytic streptococci, and this was probably a secondary infection. In two of the cases (Cases 12 and 13) the infection travelled in the reverse direction—that is, from the patient's vagina to her throat, which, though free from haemolytic streptococci at the onset of the illness, became positive during the course of a puerperal infection caused by haemolytic streptococci. Therefore, despite the fact that I do not report an instance of genital infection from the patient's throat, we may deduce that they will be found in a larger collection of cases.

The Throat Carrier Theory.

As far as I am aware, Kanter and Pilot[9] were the first to suggest that puerperal infection could be caused by the "spraying" of organisms on to the patient from the throat of her attendant during labour. Attention was recently focused upon this etiological factor by the publication of a report upon an outbreak of puerperal sepsis by Watson and Menely.[10] The authors confess that their observations were inconclusive in regard to the mode of spread of the infection, but they based their prophylactic measures entirely upon the assumption that "throat carriers" were a prime factor in the epidemic.

Case Records.

I am aware that the cases which I am about to report do not furnish conclusive proof that the patients were infected from the throats of attendants, but the cumulative effect of the evidence is very striking, and shows, I believe, a prima facie case for further investigation. I will begin with the account of some cases which occurred in two maternity hospitals—one of which is in Sheffield—which I will call Hospital "A" and Hospital "B."

Cases in Hospital "A."

The pyrexial rate in this hospital, which is to some extent a special hospital (in that no "emergencies" are admitted), is 0.8 per cent., and the B.M.A. morbidity, which includes deaths from all causes, was 1.25 per cent. These figures show that the technique for the conduct of labour was efficient, and they emphasize the consternation which was caused when an acute case of haemolytic streptococcal infection took place.

Case 1.

Mrs. O., aged 28, a 2-para, was delivered naturally at full term on January 8th, 1929. She came into hospital thinking she was in labour, but, as there was no sign of its onset after six days it was induced by castor oil and quinine. No vaginal examinations were made. The rectum was examined twice. The delivery was conducted by Sister B. and Nurse S. A small perineal tear was sutured in the lithotomy position by house-surgeon "No. 1." It is of importance to note that no haemolytic streptococci were found in a routine swab taken just before the perineal repair, so that the patient was not then infected.

On January 11th her temperature rose to 103°; pulse 140. A second culture from the vagina gave a heavy growth of haemolytic streptococci.

Result.—The patient recovered after the temperature had been elevated for fourteen days.

The antiseptic used was mercury biniodide. The skin was painted with iodine before the perineal suture. Sterile gloves and gowns were worn, but no masks.

An extensive bacteriological investigation was undertaken by the bacteriological department of the Sheffield University. The results may be summarized as follows.

Table III.

Name.	Source.	Haemolytic Streptococci.	Remarks
Mrs O.	Vagina just after delivery	Negative	—
Mrs. O.	Vagina third day	Positive	Heavy growth
Mrs. O.	Throat, 5th day	"	A few colonies
Mrs. O.	Urine, 5th day	"	A few colonies
H S. No. 1	Throat and nose	"	Sutured perineum
Sister B.	Throat and nose	"	Delivered
Nurse S.	Throat and nose	"	Delivered
Nurse N.	Throat and nose	"	Nursed afterwards
Nurse K.	Throat and nose	"	Nursed afterwards
Charwoman ...	Throat and nose	"	No contact with patient
Remaining nurses and non-professional staff (11)	—	All negative	—
27 patients... ...	Throat, nose, and vagina	All negative	Five in same ward
Surgeon	—	Negative	Rectal examination before labour

The blankets and dressings were sterile.

The facts arising out of this are:

1. The patient had no haemolytic streptococci in the vagina immediately after labour, but there was a profuse growth on the third day when the temperature rose. The same organism was recovered from her throat some days later. It is impossible to determine whether this was the primary or a secondary infection; or whether the throat was infected by one or other of the "carriers" either during or after labour.
2. Six apparently healthy persons out of fifty examined were found to have haemolytic streptococci in their throat and noses; three of them were directly concerned with the delivery. Two others performed nursing duties, including toilet of the vulva, during the first three days of the puerperium.
3. The charwoman had haemolytic streptococci in her throat and nose. She was in frequent contact with the nursing staff, but had no contact with the patient or the house-surgeon No. 1.
4. None of the 27 patients was found to harbour the organism in throat, nose, or vagina.

All the staff who were found to be infected were kept off duty. One of them developed a severe haemolytic throat some days later.

From this time, masks made of turkey towelling, covering the mouth and nose, were worn for all deliveries. They were not used until six months later (after Cases 2 and 3) for post-partum nursing. During the ensuing six months there were no cases of pyrexia, and, though numerous ante-partum and post-partum vaginal swabs were taken,

haemolytic streptococci were found. In July the accidental demonstration of haemolytic streptococci in the vaginae of two patients on the same day led to a bacteriological examination of the throats of the whole staff, and those of the two patients and their husbands. The details of the cases are as follows.

CASE 2.

Mrs. G., aged 27, a primipara, was delivered spontaneously at full term on July 9th, 1929. A small laceration was sutured. No vaginal examinations were made. The rectum was examined twice. *The antiseptic used was mercury biniodide.* Sterile gloves, gowns, and masks were worn.

On July 10th a purulent discharge from the baby's eyes led to a swab being taken from the mother's vagina, from which haemolytic streptococci were grown. This organism was not present in the throat. The puerperium was afebrile and the perineum healed well. The patient was swabbed *during the first* twenty-four hours by Nurse W. and Nurse B., who were subsequently proved to be "carriers." The throats of the patient, her husband, and the whole staff were negative.

CASE 3.

Mrs. C., aged 33, a 2-para, was delivered spontaneously at full term on July 9th, 1929. A superficial laceration was sutured. One vaginal and two rectal examinations were made during labour. Antiseptic measures were the same as for Case 2.

Immediately after the delivery of the placenta the nurses were called away to another case, and Nurse B. carried out the rest of the post-partum toilet *unmasked*. This nurse was subsequently proved to be a throat "carrier."

On July 10th a discharge from the infant's eyes led to a vaginal swab being taken from the mother, from which haemolytic streptococci were grown. The organism was not present in her *throat or in her husband's. There was no rise of temperature* during the puerperium, but the perineum did not heal by first intention. The two nurses were excluded from the wards.

The infection was apparently communicated to the patient in Case 2 from the throat of either of the two nurses who attended to her during the first twenty-four hours of the puerperium. The patient in Case 3 was probably infected from the throat of the nurse who carried out the post-partum toilet. The use of masks was therefore extended to all post-partum nursing.

No further cases of infection were discovered during the following three months. A re-examination of the whole staff was again undertaken in September because a patient developed a sore throat (non-haemolytic as it proved), but no "carriers" were found. In November, for a similar reason, the staff were again examined. On this occasion one nurse (Nurse F.) was found to have haemolytic streptococci in her throat. She was sent off duty, but inadvertently was allowed to return to the wards after one negative throat examination instead of three. This swab was probably negative as the result of recent gargling, because a few days later she was found to be again positive, and remained so for a long time.

She was a possible source of infection to a patient with whom she was in contact in the ward for two days. This patient (Mrs. B.) was found to have haemolytic streptococci in her vagina when her membranes ruptured two days after admission. No examinations had been made. Morphological differences in the organisms obtained from the patient's vagina and the nurse's throat raised a doubt as to their identity, so that this case is not included in his series.

The facts concerning these cases may be summarized as follows: During the year haemolytic streptococci were isolated from the vaginae of four patients. Two (Case 1 and Mrs. B.) had pyrexia. Case 1 was associated with six carriers. Mrs. B. was associated with still another carrier, but the identity of the two strains was open to doubt. Of the four patients, only Case 1 had haemolytic streptococci in her own throat. There have been no further infections in this hospital.

Cases in Hospital "B."

This hospital is a training school for midwives, and it employs outside midwives to give "district" experience to the pupils. The pyrexial rate for the past year has been 1.2 per cent., and the British Medical Association standard of morbidity, including deaths, was 6.45 per cent. These figures show how efficiently the work of the hospital has been done.

The history of the outbreak begins with a case of haemolytic streptococcal infection in a "district" case, whence infection appears to have spread to the hospital itself. The pupils resided in the hospital, and were, of course, in close contact with other nurses. The midwives lived in their own homes. The details of the cases may be tabulated as follows.

TABLE IV.—*Cases Arising in Connexion with Hospital "B."*
Antiseptic Methods: "District" cases, lysol; hospital cases, lysol and sterile gowns; no rubber gloves and no masks

* The first date is that of delivery, and the second (in brackets) that of onset of fever.

† Reported by courtesy of Mr. J. Chisholm.

‡ Reported by courtesy of Professor M. H. Phillips.

I have only seen the charts of Case 7, which show that patient was infected, but no bacteriological information is available.

It will be observed from the above table that in this outbreak ten patients became septic, and nine of them were proved to have haemolytic streptococcal infections, and, although there was no bacteriological examination in Case 7, her infection was probably of the same nature. Five of the patients were confined in their own homes, and four of them had spontaneous deliveries. All of these five were attended by Pupil X., who was subsequently proved to be a throat carrier. Midwife E. (throat positive) was with Pupil X. for four of the cases, and Midwife P. (throat negative) for the fifth.

Pupil X. appears to have been the innocent cause, not only of infecting these five "district" cases, but also of communicating the infection to her fellow nurses in the hospital itself; *for on December 18th the patient, Case 7,* who was delivered in hospital by Pupil Y. (throat positive), became septic. Then in quick succession five other women developed acute haemolytic streptococcal infections. Pupil Y. was a direct contact with five out of the six, though other positive "carriers" were concerned with some of the patients.

The matron reports that the health of the nursing staff was excellent up to December 21st, when, two days after the first septic case in hospital, a nurse developed a septic finger. Within a fortnight five other nurses were laid up with septic fingers or sore throats. Two nurses developed symptoms rather suggestive of scarlet fever, which were, perhaps, examples of streptococcal rash *so often seen* in

puerperal fever. The throats of the remaining twelve nurses were examined for haemolytic streptococci and six were found to be positive. It was impossible to send all the carriers off duty, so they were instructed to use antiseptic throat sprays, and those who had not had scarlet fever were given a prophylactic dose of scarlet fever antitoxin. Masks were ordered to be worn for all deliveries and for post-partum swabbing. These measures appear to have been successful, for no further cases of infection have occurred amongst either the patients or nurses up to date (five weeks).

Isolated Cases.

The evidence afforded by the following eleven instances of puerperal infection from haemolytic streptococci is all the more forcible in that the cases were unrelated with each other, and therefore the possibility of "herd" infection is eliminated. In ten cases direct contacts with the patient during labour were found to be positive throat carriers. In Case 23 the husband alone was positive, but the nurse refused to have her throat examined. The husband's throat must always be regarded as a possible source of infection to his wife's vagina.

TABLE V.—*Isolated Cases.*

Antiseptic Precautions: Records are incomplete, but where known lysol was used (violet-green once). Gloves were rarely worn.

† Present during labour. ‡ Included as controls.

§ Haemolysis of streptococci not recorded, but presumption very strong.

Case 17 is reported by courtesy of Mr. J. Chisholm. The child had *erysipelas.*

In eight out of the eleven cases recorded in Table V labour was natural, and in two it was operative. In another, though eventually delivered by Caesarean section after three days in labour, trauma was not a factor in the infection, because haemolytic streptococci were found in the cervix on admission to hospital. No attempts had been made to deliver before she was sent in, though a number of vaginal examinations had been made.

SUMMARY OF CASES.

An analysis of the twenty-four cases here reported brings out the following points: eleven of the patients were primiparae, and thirteen had had one or more children. Labour was *natural in twenty* (83.5 per cent.) and operative in four (16.5 per cent.). Some form of lysol was the most commonly used antiseptic, but cases occurred in spite of the use of efficient antiseptics, and of every modern aseptic method except masks. No further cases occurred after masks were worn, in spite of the fact that in Hospital "B" known carriers had to be kept on duty.

DISCUSSION.

The correspondence between the average mortality (1911–24) from puerperal sepsis, as reported by the Registrar-General, and the incidence of haemolytic streptococcal puerperal infections admitted to the Jessop Hospital during the past year confirms the accepted opinion as to the importance of this organism in puerperal fever. It also suggests the presence of a common etiological factor.

I have shown that, while the rate of puerperal sepsis remains more or less constant throughout the year, puerperal infections by haemolytic streptococci are highest in the winter. Infections of the throat by this organism are most common during the same season, and it is almost impossible to resist the deduction that these two facts are correlated. From the ease with which haemolytic streptococci are killed, and the fact that in some cases sterile rubber gloves were worn, it is very improbable that the organisms were conveyed to the patient from the hands of the attendant. Further, it has been shown that handling is not of itself a factor in the spread of the disease, for the natural labours had the highest proportion of haemolytic streptococcal infections (46.5 per cent.), and septic abortions the lowest (5.0 per cent.).

Pre-natal infection of the vagina by haemolytic streptococci is a possible explanation of the winter incidence of puerperal sepsis from this organism, but, as I have shown, the suggestion is unsupported by positive evidence, and the facts which are known weigh against it. When the organism has been found in the vagina during pregnancy (excluding labour itself) it has not caused puerperal fever. Further, if it were a frequent inhabitant of the vagina, operative deliveries and criminal abortions should carry the highest, instead of the lowest, proportion of haemolytic streptococcal infections.

Genital infection from a remote focus of haemolytic streptococci in the patient herself must be a danger to every parturient woman. In this series of cases no such focus was found. The rectum has often come under suspicion as a cause of puerperal infection, and while I have no direct observations, on account of technical difficulties, upon the frequency of haemolytic streptococci in the faeces, strong negative evidence against their presence is found in the immunity of even extensive vaginal operations *from this type of infection.*

It appears, therefore, that neither the patient nor the hands of her attendants are, in fact, the general source of infection by haemolytic streptococci. On the other hand, the supposition that the patients are infected from the throats of attendant carriers affords an explanation of the facts as we know them in regard to puerperal fever. We can understand how a patient can become *infected* in spite of conscientious antiseptic technique during labour; and how the "B.B.A." patient, even *without* a vaginal examination, can be infected by the nurse who attends to the post-partum toilet. The theory explains why the risk of puerperal sepsis is highest in maternity hospitals, for one carrier in an institution may spread the infection to throats of others of the community, thereby increasing the number of infected units who are *capable of* "spraying" infection on to the patient in labour. The same explanation is applicable to the higher rate of puerperal sepsis in the towns than in the country.

In support of the theory, I have submitted the records of twenty-four cases in which the patients were apparently infected from the throats of the attendants. Indirect evidence is also afforded by the fact that the use of masks stopped the epidemic in Hospital "B," and prevented a recurrence in Hospital "A." Still another line

which adopted the use of masks seven months ago has had no case of haemolytic streptococcal infection (except one which was infected on admission) during the whole of this time, whereas previously such cases occurred with sufficient frequency to cause grave anxiety.

I conclude, therefore, that the spread of haemolytic streptococcal infection from the throats of carriers to women in labour is a factor in the etiology of puerperal fever which requires most careful investigation from every possible angle.

PROPHYLAXIS.

To those who are prepared to take prophylactic measures upon prima facie evidence, and before absolute proof is obtainable, I would make the following suggestions:

1. Masks of suitable material, completely covering the mouth and nose, should be worn by *all* persons present whenever the vulva is exposed during labour or the puerperium.
2. The occurrence of even a mild sore throat in the private home of an expectant woman should necessitate a careful bacteriological examination for haemolytic streptococci. If positive, search should be made for other domestic carriers. In any case, the patient's throat and vagina should be examined for haemolytic streptococci.
3. In institutions nurses and patients with even slight sore throats should be isolated from lying-in wards.
4. In institutions the first rise of temperature should necessitate an immediate vaginal or cervical test for haemolytic streptococci. If positive, the throats of contacts must be examined, and any carrier removed from the wards.
5. Doctors in private practice should have their throats examined at frequent intervals. If they have a case of puerperal sepsis, they should, for their own protection, have the throat of the patient and of all contacts examined.
6. It should be part of the duty of the Local Supervising Authority to have examinations of the throats of midwives who are concerned with cases of puerperal fever.

RECOMMENDATION.

There is enough evidence for the throat "carrier" theory to justify a full investigation. The time for isolated study has gone by, and some authoritative body should plan and control the research in selected areas. The full co-operation of the profession, and of the public health services would be essential, but, above all, the bacteriological work must be above suspicion.

The deductions made in this paper depend entirely upon the very expert bacteriological work which has been so ungrudgingly carried out in the department of bacteriology (Professor J. S. C. Douglas) by Dr. Edington in the University laboratories, and by Dr. Kirk in the laboratory attached to the Jessop Hospital for Women. The county bacteriological departments at Derby and Wakefield have also given most valuable assistance in the examination of contacts.

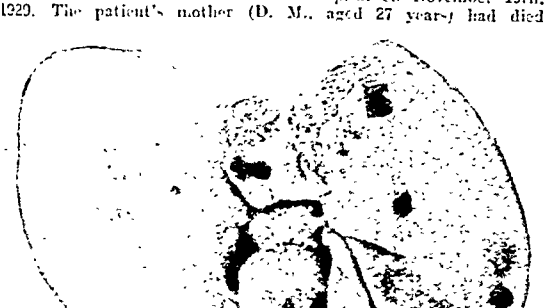
SPONTANEOUS INOCULATION OF MELANOTIC SARCOMA FROM MOTHER TO FOETUS.

REPORT OF A CASE.

BY

F. PARKES WEBER, M.D., F.R.C.P., E. SCHWARZ, M.D., M.R.C.S.,

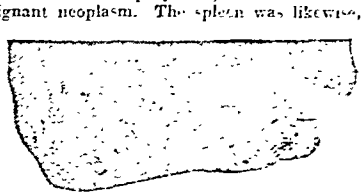


AND

R. HELLENSCHMIED, M.D.

(From the German Hospital, London.)

THE following is, we believe, the first reported case of transmission of a malignant neoplasm from mother to child by spontaneous inoculation.



The child, B. M., aged 8 months, a well-developed boy of normal size, was admitted to the German Hospital on November 19th, 1929. The patient's mother (D. M., aged 27 years) had died

Inferior surface of the liver showing melanotic tumours.

at the German Hospital on July 4th, 1929, of melanotic sarcoma with visceral and subcutaneous metastases. There was no post-mortem examination, but she was known to have been suffering from melanotic sarcoma for a long time previously. Eighteen months ago she had undergone operation at the London Hospital for melanotic sarcoma of the thigh. The child was delivered on April 9th by Caesarean section at full term at the London Hospital, and was thought to be quite normal at birth. Development seemed to be satisfactory till recently, when enlargement of the abdomen and a somewhat cachectic appearance of the skin was noticed.

On admission to the German Hospital the liver was found to be enlarged, reaching down to the umbilical level and some large, hard, rounded nodules could be felt projecting on its anterior surface, suggesting malignant neoplasm. The spleen was likewise, but evenly, enlarged, its lower border (on palpation) being three fingerbreadths below the costal margin. Otherwise the child seemed fairly healthy and quite lively and happy at first, excepting that at times there was moderate fever. Nevertheless, after some time the child began to show increasing cachexia. The Wassermann and Meinicke reactions were negative, and so was Pirquet's cutireaction for tuberculosis. The blood count (November 22nd) was: haemoglobin 76 per cent., erythrocytes 4,620,000 per c.mm. of blood, colour index 0.81, white cells 12,400 (polymorphonuclear neutrophils 32 per cent., lymphocytes 57 per cent., monocytes 10 per cent., eosinophils 1 per cent.); nothing abnormal was noted in the appearance of the red cells.

Lower portion of the upper surface of the right lobe of the liver, showing the melanotic tumours felt during life.

The liver and the bosses on it probably increased somewhat in size, but certainly only very slowly. About the middle of January, 1930, the child, who was gradually losing in weight and becoming more cachectic and obviously ill, developed considerable fever and left-sided purulent otorrhoea. The blood count on January 13th was: haemoglobin 60 per cent., erythrocytes 4,320,000 per c.mm., colour index 0.7, white cells 16,550 (myelocytes 4 per cent., metamyelocytes 10 per cent., polymorphonuclear neutrophils 36 per cent., lymphocytes 45 per cent., monocytes 4 per cent.). The pyrexia continued, and the child died on January 24th.

We may say here that the child's urine throughout, whenever examined, was clear and of a golden brown colour, sometimes deeper than at other times. It was free from albumin, sugar, indican, acetone, diacetic acid, and excess of urobilin or urobilinogen. The colour deepened when the urine was kept, but never became blackish. Only on one occasion (January 15th) was a supposed positive reaction for melanogen obtained—that is to say, on using the potassium nitroprussiate (Legal's) test for acetone we obtained a *deep* green coloration on addition of the glacial acetic acid, but this test is of doubtful value.

Necropsy (January 25th).—There were several minute subcutaneous melanotic nodules scattered over the front and back of the thorax of the emaciated child. The liver was enlarged (weighing 455 grams after being kept for some days in alcohol), and several melanotic rounded tumours (up to the size of a pigeon's egg) projected under the capsule, notably those that had been palpated during life in front of the liver. The spleen was moderately enlarged (weighing 100 grams), but was otherwise not

abnormal in appearance. There were a few minute subpleural melanotic patches in the lungs, and some small melanotic nodules were attached to the periosteum at the back of the anterior wall of the thorax. Many of the abdominal lymphatic glands showed melanotic infiltration; one or two of these glands were adherent to the kidneys and pancreas. Otherwise macroscopically the viscera appeared normal. We were not permitted to examine the head and central nervous system.

Microscopical Examination.—The melanotic tumour cells were typical in all the pieces of growth. The small nodule in the liver which we examined was found to be surrounded by a kind of spurious capsule, due to compression of the neighbouring tissue, and suggesting that the tumour growth had not been very rapid, but there were also melanotic tumour cells outside this spurious "capsule," and many of the Kupffer "Sternzellen" in the neighbourhood contained melanin granules. A piece of lung showed minute broncho-pneumonic areas, as well as a minute subpleural melanotic growth. A tiny subcutaneous nodule appeared to be encapsuled by the distended wall of a capillary blood vessel. Pieces of pancreas and kidney showed nothing abnormal, but a small lymphatic gland adjacent to the pancreas was infiltrated with the melanotic growth. A lymphatic gland removed from the right inguinal region was free from melanotic growth, and so was the piece of spleen examined. The slight splenomegaly was apparently due to increase of the splenic pulp. The Malpighian follicles of the spleen were not large, and contained very little "germ-centre."

Remarks.

The main facts of the case may be shortly stated as follows. A woman known to be suffering from melanotic sarcoma was delivered, three months before her death, of a child who appeared at first to be healthy. When 8 months old the child was admitted to hospital with an enlarged liver on which bosses could be distinguished by palpation, suggesting a malignant neoplasm. With increasing cachexia the child died at 10¼ months of age, minute nodules having developed beneath the skin shortly before death. The post-mortem examination showed that the bosses which had been felt in the liver were melanotic tumours. The size of the growths suggested that the primary infection was in the liver, but there were many infiltrated lymphatic glands in the abdomen and minute metastases in the lungs and in the subcutaneous tissue. Palpation during life and examination after death pointed to the growth of the neoplasm in the liver having been rather circumscribed and slow, as if there was considerable resistance on the part of the child's tissues. The tumour cells from which the growths in the child's liver had developed had evidently been carried to the hepatic capillaries (via the blood stream in the umbilical vein) from the placenta, which is known to have been melanomatous.

The splenomegaly noted by us in the child may be compared to that which has been occasionally known to be associated with hydatid disease of the liver. The spleen of infants and children becomes readily enlarged from any toxic or distending cause. Thus, the spleen was enlarged in a boy with hydatid disease of the liver shown by A. F. Voelcker at the Medical Society of London in November, 1907. A certain amount of splenomegaly was still present in February, 1909, after successful treatment by drainage of the hydatid cyst, when Dr. Voelcker again showed the case.[1] In our case the following note kindly given us by Mr. Eardley Holland, who performed the Caesarean section on the mother at the London Hospital, makes it certain that melanotic tumour cells must have passed from the mother through the placenta (owing to actual melanotic metastases in the placenta) into the foetal blood stream. The blood in the umbilical vein having chiefly to circulate through the liver, some of the melanotic cells were caught up in the hepatic capillaries, and these cells were the parents of the multiple melanotic tumours (the "primary" tumours, as far as the child was concerned), some of which could be palpated in the enlarged liver when the child was eight months old.

This is the note by Mr. Eardley Holland, who is going to publish separately an account of the case from the obstetrical and gynaecological point of view.

"I saw the mother in consultation with her doctor on April 5th, 1929. She was an ill woman, in about the thirty-eighth week of pregnancy, with multiple melanotic nodules scattered liberally beneath the skin of the abdomen and thorax. The uterus was above the usual size at term, and a large soft mass occupied the lower segment. On April 9th I delivered a live child by Caesarean section. The lower uterine segment was occupied by a huge black placenta, which proved to be infiltrated with mass of melanotic growth. The mother made a smooth recovery, and the child left the hospital thriving and without evidence of disease."

There are many remarkable published examples of different varieties of inherited constitutional predisposition to malignant neoplasms.[2] Especially notorious is the case of constitutional predisposition due to familial multiple polyposes of the large intestine.[3] We would suggest that J. S. Manson's examples of the "hereditary transmission of sarcoma" (mother and two sons affected with lymphosarcoma)[4] were examples of inherited constitutional predisposition to lymphosarcoma, and analagous to rare cases of familial tendency to lymphatic leukaemia,[5] which, like myeloid leukaemia, is probably also of neoplastic origin. Our present case, as above stated, has nothing to do, as far as we can judge, with any inherited constitutional predisposition to malignant neoplastic growth.

It is, as mentioned above, apparently the first case of the kind reported in human pathology. We have not ever heard of any analogous case in animals—that is to say, a case of congenital malignant tumour due to intrauterine inoculation of the foetus by the passage of malignant tumour cells from the placenta to the child by way of the umbilical vein. Nature's experiment in the present case could only be imitated in experimental animal pathology by inoculating the blood stream of the umbilical vein at the moment of birth with a dilute emulsion of tumour cells obtained from a sarcoma or carcinoma that had previously developed spontaneously or had been artificially produced in any part of the mother's body.

Professor J. A. Murray has, however, kindly referred us to a paper by Dr. Makoto Takahashi,[6] who also quotes similar experimental work carried out by other investigators on rats or mice. Takahashi produced growths in the lungs by the intravenous injection of carcinomatous or sarcomatous material. He found that a large proportion of the cells introduced into the blood stream disappeared after undergoing vacuolation, surrounded by leucocytes. Although the lung capillaries formed an efficient filter some tumour cells were able to pass through the lungs and give rise to growths in various parts of the body. The cells which passed through the lungs and were disseminated in that way exhibited a predilection for a limited number of sites.

In regard to the last-mentioned "metastatic predilection" we might add that the author did not refer to the wonderful examples of the predilection in human pathology of metastases from particular tumours for particular sites—for instance, the predilection of metastases from the Hutchison type of suprarenal medullary "sarcoma" (neuroblastoma) in children for the orbits and skull, and the generalized infiltrating metastatic osteogenic carcinomatosis of the skeleton occasionally resulting from a primary carcinoma of the prostate gland.[8] Such examples might be compared with the secondary pyaemic foci limited to the lung skeleton, which formerly occasionally occurred in septic cases.

In regard to the way in which in our case the maternal melanotic tumour inoculated the foetal circulation by "growing through" the placenta, an analogy may be found in what happens in cases of true congenital tuberculosis, but, of course, tubercle bacilli are much less likely to be held up in the blood capillaries of the foetal liver than are large tumour cells. Some years after Koch's discovery of the tubercle bacillus it was maintained that the bacillus could not pass through the placenta and infect the foetus in utero, and it was held that only a constitutional predisposition towards tuberculosis could be inherited, and even that was denied by many authorities. However, it was soon proved that in very rare cases the foetus was actually infected in utero owing to the tuberculous process in the mother infecting the placenta, and producing one or more tuberculous lesions in the placenta. By means of such placental lesions the tubercle bacilli were enabled to "grow through" the placenta, with a resulting tuberculous inoculation of the foetal circulation and true congenital tuberculosis. It was alternatively but less convincingly suggested by A. Sitzenfrey, in 1909,[9] that tuberculous foci localized in the decidua vera, might penetrate the amnion, infect the liquor amnii, and thus give rise to intrauterine infection of the foetus—indeed, F. W. Andrewes[10] already

in 1903 had suggested that pre-natal tuberculosis might in some cases possibly be caused by the foetus swallowing liquor amnii containing tubercle bacilli derived from a disintegrating lesion of the placenta. How rare cases of true congenital tuberculosis must be may be judged by the fact that in 1916 one of us was able to summarize all the hitherto proved and probable cases of true congenital tuberculosis in a short article published in the *British Journal of Children's Diseases*.[11]

In our present paper it would perhaps have been better to use the term "malignant melanoma" instead of melanotic sarcoma, as it might possibly be suggested that the primary growth in the mother (the site of which is not certain) was a melanotic carcinoma. The tumours in the child's liver were obviously of multiple metastatic type, and it is the absence of any primary tumour in the child that makes the case unique, the real primary growth having been, of course, in the dead mother. The inoculation of the child may have taken place not long before, or even at, birth.

The liver, now in the museum of the Royal College of Surgeons of England, was demonstrated by us on February 28th, at the Section for the Study of Disease in Children, of the Royal Society of Medicine.

APHONIA, DYSPHONIA, AND THE "SINGER'S ATTITUDE."

BY

SIR JAMES DUNDAS-GRANT, K.B.E., F.R.C.S., M.D.

AT the last meeting of the Section of Laryngology of the Royal Society of Medicine I referred to my application to the treatment of functional aphonia of Mr. Negus's observation that in certain animals, particularly the climbing ones, the efforts made with the fore limbs were accompanied by an approximation of the vocal cords. Mr. Negus kindly placed at my disposal an apparatus containing a strong spiral spring, which resisted the pressure made by the hands on the two ends. The result was most satisfactory, as the involuntary approximation of the cords added a valuable additional factor in the restoration of voice. I found that in the absence of the spring-pressure instrument a similar result was obtained by making the patient press together my hands or those of a nurse standing behind her (or him). This procedure helped to restore the voice with less frequent resort to the distressing faradic stimulation which is sometimes inevitable.

In the treatment of singers suffering from functional difficulty in voice production with paresis of the internal tensors or transverse arytenoid muscles (elliptical glottis or posterior triangular gap) I have found this "arm-adduction" pressure most helpful. The following is a recent case in point.

Miss Y., aged 23, a contralto of considerable ability who had been studying singing for over a year, found that for some weeks her voice was husky and the "attack" uncertain. The laryngoscope showed imperfect approximation of the cords, the vibrating parts of the cords having an elliptical opening between them and the cartilaginous portion a triangular one. The "arm-adduction" against resistance was followed by an approximation of the cords to almost the normal degree, and with it a great increase in the certainty of the "attack." The confidence in herself, which is of such importance to a singer, was again established, and she was at once able to apply the appropriate general principles inculcated by her teacher with every success.

The "attitude" adopted by many singers in which the hands are held together as in prayer, or in holding a little book of the words, is in most cases probably a fashionable affectation, but it may become an extra help in producing approximation of the cords if the hands are not merely in contact but compressed together. I can conceive this application of the attitude described as being of great use to a singer. It should, however, be accompanied by the lower lateral costal method of breathing, which is, for singing purposes, probably the best.

Among other ancillary helps towards combating the perverse gaping of the glottis in functional aphonia I find induction of the "inspiratory phonation" of the vowel sound "ee" followed by the expiratory "aw" effective in spite of, or, perhaps all the more, on account of, the grotesque effect. Another adjunct is the application of "Bárány's noise-box" to the two ears while asking the patient such a question as he may be anxious to answer. If the noise is suddenly turned off while he is giving his answer he may be surprised at the discovery that he is talking in a loud or even shouting voice.

I am grateful to Mr. Negus for his masterly investigation, and am pleased to have given it immediate clinical application.

A NOTE ON DISSEMINATED SCLEROSIS.*

BY

FOSTER COATES, M.D., D.P.H.,
PHYSICIAN, ROYAL VICTORIA HOSPITAL, BELFAST.

DISSEMINATED sclerosis is one of the most common organic diseases of the nervous system met with in Northern Ireland, and apparently occurs more frequently here than in other parts of the world. In the Royal Victoria Hospital, Belfast, 728 cases of disease of the nervous system were treated in the wards during the past three years, this total including neuroses, psychoses, epilepsy, chorea, and neuritis; 105, or 14.5 per cent., of these were cases of disseminated sclerosis. I have analysed 100 cases, 40 of which were under my own observation. From this analysis I have obtained statistics regarding the sex, age, and occupational incidence, also mode of onset and relative frequency of certain symptoms. Doubtful cases were rejected, and the possibility of syphilis was invariably excluded.

ETIOLOGY.

Although the disease is stated to be equally common in males and females, I found that males were more frequently affected, the proportion being 3 to 2 (males 61, females 39). The onset is most common between the ages of 20 and 40; the average age at onset was 29, the youngest patient being 11 years and the oldest 59. Five children under 15 were affected, and three adults over 50. As regards occupation, two-thirds of the patients were town workers and one-third country workers; 10 per cent. were farmers. The hospital records show that in 1927, out of a total of 5,459 in-patients treated, 540, or 10 per cent., came from the country, and 157, or 3 per cent., were farmers.

This would seem to indicate that disseminated sclerosis was three times more prevalent in farmers and in people living in the country than among those dwelling in towns. To check this I analysed another series of medical cases (heart and kidney), and found, somewhat to my surprise, that the proportion of country cases was only 10 per cent. and farmers 2 per cent. From these findings there would seem to be no doubt that disseminated sclerosis is more common among those living in country districts. The occupational statistics which I have given do not seemingly support the contention that this disease is more common in wood workers.

Heredity seems to have no bearing on the incidence of infection. Even in families with a definite neuropathic history disseminated sclerosis does not necessarily show

* Condensed from a Presidential Address delivered to the Ulster Branch of the British Medical Association.

itself. It is said to be exceedingly rare to have more than one case in the same family. Since preparing these statistics I have seen a brother and sister affected, and have been told of another brother and sister suffering from this disease.

I do not propose to discuss the question of the specific causative agent; it will suffice to say that, although considerable evidence has been brought forward in favour of a spirochaetal infection, this has not yet been definitely proven. It has been suggested that the infection might be transmitted by an insect bite, but, owing to the sporadic occurrence of these cases, I think that this is unlikely. In the cerebro-spinal fluid there is, as a rule, no definite change, except perhaps a slight increase in the cell content. In my cases the average number of cells present was 6, but in a few cases no cells were found.

Clinical Features.

There are two distinct types of this disease: (1) the slowly progressive case with insidious onset; and (2) the case in which there is an acute onset, with striking remissions and often apparent cure. I feel inclined to believe that these types may constitute two separate clinical entities. Other types are described, depending on the part of the nervous system which is chiefly affected; these are: the spinal cord type; the cerebral type (headaches, dizziness, diplopia, optic atrophy, etc.); the cerebellar type; and the hemiplegic type.

Onset.—In 79 cases the onset was insidious, usually with weakness and ataxia of lower limbs, and frequently preceded by pains, tingling, or numbness. In 21 the onset was sudden. In 10 cases temporary diminution or loss of vision was the first symptom; in 6 cases diplopia; and in 3 cases headache and vomiting. Two cases started as hemiplegia, and afterwards developed the typical signs of the disease.

Remissions.—When the onset is insidious the course of the disease tends to be slowly progressive, with occasional partial remissions. When the onset is acute, complete, or almost complete, remissions are frequent. There were definite remissions in 25 per cent. of these cases. In one case there was a remission, with complete recovery for eleven years, before further symptoms developed.

Another patient of mine had a number of striking remissions.

This patient became ill thirteen years ago with paresis of left arm and leg, which cleared up completely. Four years later he was laid up for a time with dizziness and nausea, without paresis. Two years after this he suddenly lost the sight of his left eye. Vision gradually returned, but about a month later his speech became thick and slurring, and he lost the power of his left arm and leg; he also complained of diplopia. He recovered almost completely from this attack, and remained well and at work for a year when he had a slight attack, involving the right side of the body, which only troubled him for a short time. The following year he had a similar attack, which also cleared up. I saw him after this, and he was quite well, except that he walked with a halt. I have not seen him for some years, but am informed that he is keeping well.

Symptoms.

The percentage frequency of symptoms is shown in the following table.

	Per cent.
Paresis or paralysis of lower limbs	97
Knee-jerks exaggerated	96
Babinski's sign present	87
Ankle clonus present	79
Alterations of sensation (chiefly subjective)	79
Modification of abdominal reflexes	77
Nystagmus present	76
Paresis, paralysis, or ataxia of upper limbs	70
Bladder symptoms (precipitancy, hesitancy, or incontinence)	49
Intention tremor	48
Atrophy or pallor of optic discs	47
Diplopia (transient)	36
Dysarthria	33
Mental change	32
Dizziness	26
Temporary loss of vision	15
Defective hearing	12
Ptosis	5

The commonest symptoms, therefore, were spastic paresis of the lower limbs, with Babinski's sign and ankle clonus (in some cases marked ataxia was the chief feature); subjective sensory changes; loss or modification of abdominal and cremasteric reflexes; nystagmus; bladder symptoms; and intention tremor.

Psychical changes are more marked in the advanced cases where delayed cerebration and mild dementia are common. Emotional instability frequently occurs. Euphoria is often a feature, but depression may occur.

The following subjective sensory symptoms are frequently noted: numbness, tingling, sensation of heat or cold, pains, headaches, stiffness, and aching feeling in back. Abdominal pain and discomfort are present in some cases. Two of my patients were operated on for abdominal trouble shortly before disseminated sclerosis was diagnosed, and no definite pathological condition was found to account for the symptoms. In another case an operation was performed for the relief of intermittent claudication of the right leg; a few months later the patient was found to be a typical case of disseminated sclerosis. Such cases would suggest that the vegetative nervous system may be involved in this disease.

Objective sensory change is not so common, but frequently careful examination reveals some definite impairment. Astereognosis occurs in a number of cases. Scanning speech in my experience, is infrequent, and, if it occurs, is only found in advanced cases. Slurring speech is much more frequent.

The course of the disease is very chronic, though acute cases have been described. Most cases last from ten to twenty years, and death is frequently due to some intercurrent disease.

Whilst the ultimate prognosis is undoubtedly grave, in a large number of cases with a fairly sudden onset and definite remissions the patients may live a useful life for many years. In a small percentage of these cases complete recovery seems to occur.

Treatment.

Since remissions are frequent, and the course of the disease is so chronic, it is difficult to assess accurately the results of treatment. Massage, electrical treatment, and re-education exercises are very important. Over-exertion is to be avoided, but patients should be encouraged to move about, if able to do so. Infection by the malarial parasite is stated to have been beneficial in some cases.

Of drugs, arsenic, hexamine, and potassium iodide are frequently prescribed. Silver salvarsan seems to be of distinct value, and appears to be superior to salvarsan in this disease. A course of seven or eight intravenous injections (0.05 up to 0.15 gram) should be given at weekly intervals till 1 gram has been administered. Not more than three or four courses should be given in one year. This seems to be a small dosage, but, in dealing with a chronic disease where treatment is likely to be prolonged for many years, it is better to err on the safe side rather than run any risk of injuring the liver, which would prevent further use of the drug.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PRIMARY OVARIAN PREGNANCY.

In view of the rarity of the occurrence of ovarian pregnancy the clinical details of a case which appears to have been of this kind may prove to be of general interest.

A woman, aged 27, who had been married for six years, had given birth to a boy after a normal labour in 1921. She had had two miscarriages, in 1926 and 1928 respectively. Menstruation was of the 3/21 type, always preceded by pain.

About midday on December 10th, 1929, severe abdominal pain developed, being most marked in the right iliac fossa and spreading across the abdomen. It was thought to be due to colic, and continued all day, but became less at night, leaving, however, soreness, which prevented sleep. On the following morning the patient was able to get up and take a little breakfast, but about midday the pain returned; it was more severe than before, and again began in the right iliac fossa, spreading across to the other side. She returned to bed and applied heat to the abdomen, but the pain did not cease, and she became exhausted. On examination, at the first visit that night (9 p.m.), the temperature was found to be 101°; the pulse was 98, thready and irregular. The patient was very blanched and partly collapsed. The abdomen was slightly distended generally, with a little resistance and tenderness over McBurney's point; vaginal examination revealed

fullness and a boggy sensation in the posterior fornix. A diagnosis was made of acute appendicitis, probably with perforation, and an immediate operation was advised.

Two hours later we opened the abdomen over McBurney's point. The peritoneal cavity was found to contain dark blood clot, so a large medial incision was made. The lower part of the abdomen and pelvis were full of blood clot, and active haemorrhage was in progress, continuing after most of the clot had been removed. No bleeding points could be found, however, in spite of the gushing of pure blood; both Fallopian tubes were healthy, and the left ovary was normal. The right ovary, however, was twice the size of the left, and there was a punctured raw area about the size of a sixpenny piece, which extended into the ovarian tissue. The ovary was therefore removed, and it was noticed that while it was being held on the stretch the haemorrhage stopped. The appendix was inflamed, tortuous, constricted at the base, and covered with adhesions; it was therefore excised. A small cystic body, about the size of a split pea, was found in the blood clot in the pouch of Douglas, but, unfortunately, this and the right ovary were accidentally lost by a probationer nurse. No further bleeding points could be found, and, owing to the bad condition of the patient, the abdomen was closed as quickly as possible. Haemoplastin was injected during the operation, and afterwards at regular intervals. The patient made an uninterrupted recovery, and was discharged from hospital a month after admission.

We came to the conclusion that this was a case of primary ovarian pregnancy, the ovum having been fertilized on the surface of the right ovary. Unfortunately the loss of the two specimens robbed us of a definite conclusive diagnosis; we are at a loss to understand how all the haemorrhage came from the small rupture in the ovary.

AN UNUSUAL CASE OF ACUTE PANCREATITIS.

THE case described below is interesting as it throws some light on the etiology of acute pancreatitis. The boy had lived on a diet containing an insufficient amount of proteins and a superabundance of carbohydrates. The pancreas was overtaxed in dealing with this excess of carbohydrates. In addition to this, the absence of a proper supply of fresh proteins possibly predisposed the pancreas to inflammatory changes. Other vitamin-containing articles were obviously taken in insufficient quantities—for example, fruits. It is difficult to avoid looking at acute pancreatitis as a deficiency disease, in some ways resembling scurvy or pellagra, after carefully studying this case.

On August 8th, 1929, a messenger boy, aged 15, cycled to a neighbouring village after his day's work. There he had a meal of chips, and then cycled home. Towards midnight he started having what he termed a "bilious attack," accompanied by slight abdominal pain and vomiting. He had been subject to bilious attacks for years, and so did not send for his doctor until late in the afternoon of the next day. Dr. Pierce saw him, and promptly sent him into the local hospital. As the boy's condition got worse we saw him together about midnight. He then showed slight rigidity of the abdominal muscles, tenderness over the upper abdomen, definite fluid in the abdominal cavity, pulse 95, temperature 99.6°. The matron of the hospital informed us that the boy showed slight cyanosis of the lips when she first saw him in ordinary daylight, and that he reminded her of cases of acute pancreatitis she had seen before. The cyanosis was not obvious in artificial light.

Operation.—At 1 a.m. on August 10th a right paramedian supra-umbilical incision was made. The abdomen contained 2 to 3 pints of clear fluid; this was evacuated. The pancreas was red, and obviously enlarged and indurated, with a thickness of 2 to 3 inches. There were no areas of necrosis, and the omental fat showed no appreciable change. A corrugated rubber drain was put down to the head of the pancreas and the abdomen closed. The drain was removed in forty-eight hours as only a slight amount of clear fluid drained out. On August 15th and 24th the patient had a "bilious attack" with vomiting, pain, and a rise of temperature to 103°, otherwise his progress was fairly satisfactory. He left hospital on September 12th, and resumed work three weeks later. Since then he has had several very mild "bilious attacks," otherwise he has been comfortable.

Since operating on this patient we have gone more fully into the history, and this proved to be very interesting. The boy had never eaten any meat or eggs in his life, but lived on potatoes, bread-and-butter, pastry, and sugar. He drank large quantities of tea and water, and sometimes milk. While in hospital he was gradually trained to eat ordinary food, and is now leading a normal life, but still has a good thirst, and a weakness for chip potatoes. He has never passed any sugar in the urine, but showed a trace of albumin occasionally while in hospital. He has always been a pale and poorly developed boy and was easily tired. The chest shows no organic disease.

Reports of Societies.

CARDIAC INFARCTION.

AT a meeting of the Medical Society of London, on March 10th, with the president, Mr. DONALD ARMOUR, in the chair, Dr. J. W. MCNEE opened a discussion on cardiac infarction, speaking from the point of view of a general physician.

Dr. McNee said that, while working at the Johns Hopkins Hospital in 1924, he saw three cases of coronary thrombosis; the clinical diagnosis was made with such certainty that Dr. McNee looked into the matter, and discovered an extensive American literature on the clinical side. Once the clinical syndrome was recognized in this country many cases were reported, and the problem was often found to affect the general physician or surgeon rather than the expert cardiologist. The real reason for the lack of differentiation of coronary thrombosis until recent times appeared to be that the great teachers on cardio-vascular disease, such as Mackenzie, Allbutt, and Osler, did not separate coronary thrombosis from angina pectoris. The distinction was now recognized as important, for the course and prognosis differed in the two disorders. Dr. McNee added that it was possible to look back through older medical literature and make the diagnosis of coronary thrombosis on the clinical history and necropsy findings, as had been done by Ryle in discussing John Hunter's cardiac infarct. The anterior descending branch of the left coronary artery was usually affected by thrombosis, which led to infarction of the walls of both cavities of the heart, so that secondary embolism might occur either in the lungs or in some area supplied by the systemic circulation. The predisposing causes of coronary thrombosis appeared to be those of arterial degeneration in general; hereditary tendency played a part, and angina pectoris was a very common precursor. Several clinical groups were definable: (1) cases in which death followed immediately upon occlusion; (2) cases in which death followed a few minutes, a few hours, or at the most a few days after the occlusion; (3) cases in which grave symptoms of myocardial insufficiency immediately followed the accident, but death was postponed for weeks or months; (4) cases with grave symptoms easily recognized, but from which the patient eventually recovered; (5) cases without grave manifestations but with sufficient symptoms to be recognized, and (6) cases with mild and uncertain symptoms in which only a probable diagnosis could be made. Dealing more in detail with the type of case with signs and symptoms where survival occurred, Dr. McNee described how the onset was sudden and had no relation to effort. Pain was present in the majority; it was sudden, sharp, and knife-like, and differed from the pain of angina pectoris in its duration and constancy. It might last for hours or days, agreeing closely with the description of "status anginosus," and in its distribution might be irregular. If situated in the upper abdominal region, as it sometimes was, the pain might lead to the erroneous diagnosis of perforated gastric or duodenal ulcer, or gall-stones. It might radiate like the pain of angina pectoris, and not infrequently left muscular tenderness behind it, while its resistance to morphine had been noted by many observers. Dyspnœa was present in every case; the colour of the face a peculiar earthy tinge with light cyanosis, was characteristic, indicating the severe shock present. Vomiting was common at the onset, and the rapidly developing cardiac failure which occurred in some cases led to pulmonary signs, which were easily mistaken for pneumonia. Fever began, as a rule, about twenty-four hours after the onset, and the leucocyte count was usually 20,000 per c.mm. or more. In the differential

diagnosis the most difficult point was to separate an attack of coronary thrombosis from one of pure angina. Other difficulties arose with regard to upper abdominal conditions, and particular confusion entered into those cases in which emboli were detached from the infarcted area in the heart. In discussing prognosis, Dr. McNee quoted a series of patients of whom 53 per cent. died from the attack; the average duration of life of the survivors was twenty-four months. There were cases on record, however, where survival in fair health had been possible for a much longer period. Treatment consisted of rest in bed, with morphine for the pain and shock. Cardiac failure had to be dealt with if it arose, and oxygen was useful for cyanosis.

Dr. J. PARKINSON dealt with the physical signs of coronary thrombosis, stressing the point that they were often less valuable than the general picture. The pulse might be regular and of moderate rate. Auscultation was almost worthless, but occasionally a pericardial rub was heard which was diagnostic in association with the characteristic pain. A fall in blood pressure was an important sign of the disease, but with so few physical signs the electro-cardiograph became of great interest. In the first stage the R-T period was raised or lowered from the isoelectric level, and in the second stage this plateau was replaced by a deep inversion of the T-wave. The third stage of convalescence was shown by a gradual return to normal. Dr. Parkinson mentioned the necessity of looking for signs of arterio-sclerosis between attacks of coronary thrombosis; the radiological appearances of the aorta were of particular help. He thought that the present knowledge of coronary thrombosis had simplified the problems of angina pectoris. The condition might initiate, complicate, or terminate cases of angina pectoris. The prognosis was always better after the first part of the attack was over.

Dr. W. C. BARNARD, dealing with the pathological side of cardiac infarction, mentioned the historical references to the condition. He took in turn the four types described by Van Leyden under the headings of sudden death, infarction, fibrosis, and mixtures of the last two. In cases where an elderly, healthy man suddenly dropped dead it had been shown, by experiments on animals, that the probable explanation was ventricular fibrillation which stopped the heart; if the patient survived, a condition of infarction developed, the area and extent depending upon the size of the coronary artery involved and the degree of change in the artery. In "massive" cases an early stage of swelling and purple colour of the part affected passed quickly into a stage where the myocardium became a pale clay colour, and reaction began in the tissues around. Polymorphonuclear infiltration occurred, and the granulation tissue formed gradually replaced the autolysed infarcted area. In the resulting scar tissue dilatation might occur, and during the stage of infarction two other accidents might happen: the heart might rupture through the infarcted area, or later an aneurysm of the heart might rupture. Over the area of infarction pericarditis was found as part of the aseptic inflammatory reaction. Out of the large number of causes of coronary occlusion only two were common—atheroma, and syphilitic aortitis. The latter affected the coronary arteries at their orifices, and it was rare to find fibrosis of the myocardium as a result of syphilitic diseases of the coronary arteries. Atheroma might occlude the coronary arteries, but it was more usual to find a small ulcer with a thrombus on it. This condition might be missed if the coronary arteries were opened in the ordinary way.

Dr. F. J. POYNTON described a case in which it appeared that emboli from a condition of phlebitis had travelled directly into the heart, producing a condition strongly resembling coronary thrombosis. A French physician had called this an example of reflex shock in the heart, and Dr. Poynton invited an explanation. He also mentioned the difficulty of distinguishing some cases of severe food poisoning from coronary thrombosis. Dr. F. PARKES WEBER mentioned the confusion existing in the earlier literature between angina pectoris and coronary thrombosis. He thought that observations upon cases of status anginosus had given the older writers the main basis for the coronary theory of angina pectoris, but, in the light of present knowledge, the worst cases of so-called angina pectoris previously described might really be examples of coronary obstruction. Sir WILLIAM WILLCOX said it was not infrequent to encounter cases of coronary thrombosis with apparently normal hearts and blood pressures; he asked for evidence that cardiac infarction could be caused by a primary thrombosis of the arteries occurring in a toxic condition. The PRESIDENT referred to a patient in whom cardiac infarction developed one week after an abdominal operation and gave rise to difficulty in diagnosis.

PSYCHOTHERAPY IN THE PSYCHOSES.

A COMBINED meeting of the Section of Psychiatry of the Royal Society of Medicine and the British Psychological Association was held on March 11th, when the subject of discussion was the treatment of the psychoses by psychotherapy.

Dr. HENRY DEVINE, who opened, said that in the early days of psycho-analysis he had hoped that a cure might be effected in some psychotic patients by elucidating the underlying conflicts which were assumed, according to the new teaching, to be the cause of the symptoms manifested. Unhappily the hope had not been realized. It would probably be generally admitted that the therapeutic possibilities of psycho-analysis were definitely limited in their scope, and that, so far as the psychoses were concerned, they were practically negligible. Similar limitations would appear to exist in respect of the therapeutic methods associated with the names of Jung and Adler. He was inclined at one time to feel that a certain type of paranoid patient should, on clinical and pathological grounds, be responsive to analytical treatment if a suitable technique could be devised, but he cited one case which had proved disappointing. As for the desirability of submitting the manic-depressive patient to psycho-analysis during the interval between his attacks, while the manic patient might be a subject of psycho-pathological study, he was, in his mania, scarcely the subject for therapeutic analysis, and, speaking from the standpoint of an institution psychiatrist, Dr. Devine had always found the depressive patient singularly impenetrable. In spite of the psychological interest of these cases, he could not but feel that the manic-depressive psychosis was the expression of an obscure disturbance of physiological rhythm. When the patient had got over his attack he might be considered as well; the sooner he returned to his life-work and forgot all about his illness the better. To submit him to analysis during his normal period was unlikely to avert another attack; it would lead him to think about his illness, and would serve to furnish him with more psychological material to which to give expression should he fall ill again. Furthermore, analysis in these cases or in incipient psychosis would seem to be not free from danger, even when utilized for diagnostic purposes. In these cases the somewhat uncourageous policy of "leave well alone" was most desirable.

Thus it must be conceded that at present there were no specific remedies, either psychological or physical, capable of curing the pathogenic psychosis. That was not to say that treatment in those conditions was of no value; on the contrary, nowhere in medicine were persistent therapeutic efforts more necessary and at times more rewarded than in the sphere of psychiatry. Although the psychiatric methods utilized with psychotic patients could not be considered causal or specific in their aims, this did not mean that they were haphazard or unsystematized. At the outset it was essential to listen respectfully to what the patient said; supplying the patient with a free outlet for his delusional beliefs afforded relief of tension, while the psychiatrist needed to obtain a knowledge of the phenomenal world of his patient. The study of the psychotic content was very important, for how else could the seemingly irrational behaviour of the patient be understood? From a practical point of view, however, it must be confessed that the morbid impressions of the psychotic could not be suggested or analysed away. Apart from physical treatment, the main task of the psychiatrist must be to develop what was normal in the psychotic patient, and to stimulate the social consciousness in the hope that the narrow, isolated, morbid psychic content—the besetting delusion, hallucination, or

fear—might melt away or be relegated to the background. The kind of stimuli upon which reliance was placed were simple and natural ones, like games, occupation therapy, music, companionship, and general conversation, all intended to assist the patient to regain the art of living. In comparison with the more technical psychiatric methods, this kind of treatment might appear unimpressive; nevertheless it was often instrumental in bringing about a partial or complete social regeneration. In conclusion, Dr. Devine said that he did not question that psycho-analysis had rendered a service to psychiatry. The emphasis it had placed on family situations and sexual difficulties gave precision and direction to the advice to the psychotic patient at a stage when he was sufficiently receptive to respond intelligently to psychotherapy. It should be said also that the mechanisms described by Freud were constantly exhibited in psychotic patients, though he did not think it possible to rationalize all that manifested itself in the psychotic content. On the whole, however, he felt that psycho-analytical practice had not kept pace with the increasing elaboration of its theory.

Dr. EDWARD GLOVER said that in practice psycho-analysts had made contact with the psychoses from two directions. One group of investigators had taken from the first a special interest in psychiatry, and had decided to employ psycho-analysis as an instrument of investigation and treatment. On the other hand, in this country at any rate, a larger group of analysts had been interested in the psychoses as one of a number of fields of study, but had ultimately been compelled to analyse psychoses because of the demands of patients who came for treatment. But although many psycho-analysts had had the treatment of psychoses thrust upon them, their previous training had qualified them in a peculiar degree to handle psychotic states. Psycho-analysis was considered primarily for transference in neuroses. The modifications necessary in treating different conditions did not imply modifications of analytical principle. The aim in all cases was to release the individual from anxiety and guilt, and analysts were compelled to take the quickest way home even if, as was often the case, it appeared the longest way round. It was true that the psychotic might appear inaccessible because of his reduced capacity for positive transference, but a great deal of his alleged inaccessibility was only a proof of the therapeutist's protective inaccessibility to him. Dr. Glover added that the problem of psychotic study in childhood had hardly yet been approached. Advances in the treatment of the psychoses would depend less on the experience of direct treatment of what were now called psychoses and more on the experiences derived from mental processes in young children, together with those derived from the treatment of infantile psychotic states.

Dr. R. D. GILLESPIE dealt with some of the reasons why personal analysis was important; dreams were often very serviceable from this point of view, also the history of the illness. Where cure of the developed condition was so difficult prevention was the more important, but prevention in this field had hardly ever been tried. With regard to occupational therapy, he thought its effect depended entirely on how it was carried out. Mrs. MELANIE KLEIN discussed the examination of the fantasies of children, and the occasional undiminished existence in older children of fantasies characteristic of the very young, a fixation which clinically gave rise to arrest of development. One of the chief tasks of the child analyst was to discover pure psychoses in children. Dr. H. YELLOWLEES said that it was a surprise to be told by Dr. Glover that it was the therapeutist, not the patient, who was inaccessible. One was quite prepared to have it said that one's clinical observations were mistaken, as probably they often were, but it was a little hard to hear that one was too clinical and too close to one's material, and that the more theoretically the problem was viewed the more likely was a solution to be found. It was a question of what was meant by psychiatric treatment: various methods of treatment, such as occupation therapy, which had been practised in mental hospitals long before Freud, were an invaluable factor in stimulating the recovery process in psychoses.

Dr. W. H. B. STODDART considered that manic-depressive psychosis was amenable to psycho-analytic treatment. He had at the present time a patient—a case of melancholia—who was just completing her analysis after three years. It had been said that analysis should proceed only during the intervals between the melancholia, but in this case he had carried it on right through every attack. They had spent thirteen hours in absolute silence; apparently nothing happened, but that time was not wasted, because during the whole of those thirteen hours the patient was reacting upon him with hatred; she had a negative transference. The results of the treatment were quite satisfactory. With regard to paranoia, he was not optimistic about curing in a particular case, but he felt that the patients could be treated psycho-analytically in order to give them insight and to a certain extent to delay the progress of the disease. With regard to dementia praecox he was very sceptical; he thought it might be not an organic disease. Dr. SYLVIA PAYNE, physician to the London Clinic of Psycho-analysis, said that evidence of lasting cure of the manic-depressive was not lacking. Freud reported two cases with no tendency to relapse after several years. Apart from curative effects, the patients experienced relief from mental stress. Without undue optimism it could be said that psycho-analysis had proved that it could do something in psychosis, and it opened a road for advance in knowledge and research in therapeutics not so far sufficiently realized.

Dr. N. G. HARRIS emphasized the importance of other branches of psychotherapy, particularly in the work of the mental hospitals. Nearly everyone who had worked for many years in a mental hospital came up against the difficulty of treatment, but he thought the value of developing in the admission ward, for example, an atmosphere of suggestion and re-education might be more explored. The post-encephalities were extraordinarily stubborn to treat, but there was a very large functional element in most of them besides the organic condition, and he had found, while treating the organic condition, that far better results were obtained if suggestion therapy and re-education were also pursued. Dr. DORIS ODLUM spoke of the personality of those who carried out the treatment as being a factor of importance. She noticed in mental hospitals and in hospitals dealing with early nervous cases that certain personalities suited certain patients and were absolutely useless in dealing with others. Some members of the staff were always unsuccessful with paranoiacs. In future perhaps, in the treatment of psychoses, personalities rather than methods would be prescribed. Dr. F. DILLON said that his experience was that a greater proportion of cases than was commonly realized were suitable for systematic treatment by the method of analysis. It was also true that this method, improperly applied, was capable of doing more harm than other methods. In his opinion, particularly with reference to psychoses, while it might not be possible to do much good by psychotherapy, they always had the power to do a great deal of harm. The danger lay in the use of ready-made rules without reference to the patient's individual requirements. In certain phases of mental illness valuable contact could be made with the patient, and there were practically always indications of underlying mechanisms in the light of which it was surprising how often a positive working transference could be achieved. There were no positions in which a delicate psychological touch was more necessary than in the psychoses. Three other points seemed to be of considerable interest in the analytical treatment of psychoses: to be content for periods with stages of provisional interpretation; to make judicious use of loosening mechanisms short of actual interpretation where the latter was considered inadvisable; and to be on the watch to head the patient away from dangerous and possibly disrupting highly charged ideas.

Dr. DEVINE, summing up the discussion, said that his own clinical experience, the writings of psycho-analysts generally and the individual study of cases, together with the discussion with his colleagues of cases which had been psycho-analysed, had given him the impression that on the whole psycho-analysis was not an effective method of dealing with psychoses, and so far he thought that there was extremely little evidence to show that it was. It was not a suitable method of effecting treatment; it enabled one to understand, not to cure.

Dr. GLOVER remarked that analysts had never held that there was no other valid method of psychotherapy, but the method had had by no means a complete trial. Not more than a dozen trained psycho-analysts were systematically dealing with psychoses at the present moment. The outlook was promising, but they were still learning. It seemed to him time that the psychiatrist who rejected psycho-analysis should realize that the methods he employed, such as occupational therapy, only differed from analytical psychotherapy in that they had no direct application of dosage and method.

THERAPEUTIC EFFECTS OF THE OESTRUS-PRODUCING HORMONE.

At the meeting of the Section of Therapeutic and Pharmacology of the Royal Society of Medicine, on March 11th, with Dr. PHILIP HANDLE in the chair, Professor E. C. DODDS (with whom was associated Dr. J. D. ROBERTSON) opened a discussion on the therapeutic effect of the *oestrus-producing* hormone.

Professor Dodds sketched briefly the history of oestrogenic preparations since 1911-12, when they were first made by the extraction of ovary with volatile solvents. For some years there was no definite method of standardization. The only criterion of activity was that when injected into animals the substance produced rutting out of season, and growth of the genitals in immature animals. From about 1920, however, a fairly elaborate method of standardization, involving a large number of animals, had been available, and the results were calculated on a statistical basis. The activity of the product had been very greatly increased, and with the advent of purer preparations sufficient solubility in water was obtained to admit of subcutaneous injection without the unpleasant local and general symptoms that followed on the early use of the material with an oily constituent. This water-*soluble concentrated oestrus*-producing substance, which had been called oestrin, was one which, when injected *subcutaneously into ovariectomized* animals, produced oestrus. In addition, the substance might be expected, *administered in the same manner*, to produce puberty in immature female animals, and to *bring about abortion in pregnant animals*. Was it justifiable to expect that this substance, however active in animals, would give similar reactions in women? The claim was made in commercial literature that such preparations would restore menstruation. This implied that oestrus and menstruation corresponded, but the majority of workers on the subject had grave doubts as to the relation between the two, for menstruation had a number of phenomena additional to the ordinary oestrus of animals. With regard to the production of puberty, this test was very difficult to apply to the human subject; while as to the production of abortion or premature labour, this was obtained fairly easily in experimental animals, but only with great difficulty in women. On these grounds some differences might be expected between the action on animals and that on the human female. Professor Dodds went on to relate particulars of an investigation in which the material used had been manufactured from the placenta and the urine of pregnant women, and tried in some 80 cases. It was put up in ampoules consisting of 10 units per cubic centimetre. The cases treated were referred to his department from the gynaecological out-patient department, and consisted mainly of patients suffering from amenorrhoea. The course of treatment consisted of 1 c.cm. (10 units) every day for two months. Of the 80 cases treated, only 62 went through the full two months' course, and of these, 28 started to menstruate, while 59 of the 62, apart from any question of the menstruation, "felt better." The results were rather better in the married than in the unmarried. Of the 32 unmarried who went through the full course, menstruation started in 10, and of the 30 married, in 12. The *reason for* this might be that the patient was older, or there might be some other reason. Although practically all the patients felt better, irrespective of the menstrual function, when in the case of some of them normal saline was substituted for the hormone preparation, they felt just as well on its continued use as they had on the material under test. Three cases in which it was desired to produce premature labour had been treated, with roughly 300 units each. In only one did delivery occur before the expected time, so that the results were quite indefinite. With regard to the question of the menopause, five cases had been treated with injections for two months, with the result that the vaso-motor symptoms were very definitely controlled, and in two cases menstruation started again. In three cases where the ovaries had been removed menstruation also started. In conclusion, Professor Dodds felt that the material should be given a very extended trial. The trouble was the great difficulty in obtaining the material. It was for clinicians to decide whether a 30 per cent. definite response among all cases treated was significant of real value. In only one case had there been any bad results.

Dr. A. S. PARKES discussed the relation between oestrus in the lower animals and menstruation. A good deal of confusion, he said, existed on that subject. The probability appeared to be that, instead of menstruation being developed, as suggested by Marshall, *into the process* of oestrus, menstruation, as found in the lower primates was actually due to a holdover of the pro-oestrus breakdown coinciding with the breakdown of the endometrium when fertilization had failed. Thus a double phenomenon was produced, resulting in menstruation. In animals which did not exhibit the same holdover of a pro-oestrus breakdown menstruation from an undeveloped endometrium which had not been acted upon by the corpus luteum previously. On this view oestrin clinically should be sufficient to cause that part of menstruation which corresponded to the delayed pro-oestrus breakdown, but would not produce that part of the menstruation which was really due to the action of the corpus luteum. Oestrin *clinically should not be expected* to produce the premenstrual congestion of the uterus normally associated *with the menstrual phase*.

Dr. L. C. RIVETT said that in three cases in which it *had been necessary to induce premature labour* oestrin had been tried. In one of these cases the substance did seem to *start labour three weeks before term*, but there again it was impossible to say whether labour would not have started spontaneously. The present idea seemed to be to simplify these female hormones and try to make it appear that there was only one of them, but there might be many more. He instanced the breast in pregnancy. In early pregnancy the breast tissue developed and became fairly active. It then remained quite stationary until after labour, when further changes took place leading to the production of milk. That seemed to him *prima facie* evidence of two hormones, one of which stimulated the breast and the other inhibited it, and until the second hormone was removed the breast did not actually secrete milk. It was possible that the effect of menstruation on the uterine gland was to produce another hormone which stimulated the ovary, and that might be the explanation of the difference in the effect of oestrin on the woman who still had her ovaries and that on the ovariectomized woman.

Dr. H. GARDINER-HILL said that Professor Dodds had supplied the preparation to St. Thomas's Hospital, where a certain number of cases of amenorrhoea had been treated. These 43 cases belonged to three groups—namely, primary amenorrhoea, primary menstrual irregularity (that is, cases which had never had the normal rhythm) and secondary amenorrhoea, or cases in which amenorrhoea developed after a period of normal menstruation. Positive results were obtained in 33 per cent. of the cases, definitely negative results in 55 per cent., and the remainder were doubtful. In the first cases treated about two dozen injections were given, spread over a period of two or three months, but in the later cases Professor *Dodds's* method had been adopted of giving a dose of 1 c.cm. daily for about ten days, and then a second course after an interval of two or three weeks, and an improvement in the proportion of positive results followed.

After Mr. DENTON MARTIN, a veterinarian, had related some facts bearing on the subject from his experience of canine practice, the remainder of the discussion was occupied with the question of the obtaining of supplies of this material. Dr. T. IZOD BENNETT said he believed that a certain Continental firm had taken out world-patent rights for all ovarian extractions, and other manufacturers

feared to infringe an international patent. This scandal had existed for ten or fifteen years, and it was high time the subject was ventilated in the medical profession. Dr. J. W. TREVAN said that a British firm manufacturing a preparation of ovarian hormone exposed itself to the risk of High Court action, with its heavy costs, and as the evidence for the therapeutic value of the material was not conclusive, as that discussion had shown, it was little wonder that manufacturers should hesitate. He thought that clinicians who wanted to use the hormone should make representations to the Board of Trade committee on patents, stating that they were hindered in their work by the non-availability of the substance. Professor DODDS said a tribute should be paid to one firm of manufacturers, Boots Pure Drug Company, without whose assistance the expensive work in which he had been engaged in his laboratory could not have been carried on.

It was remitted to the Council of the Section to consider what, if any, action could be taken on the question of the patent.

RENAL OEDEMA.

AT a meeting of the Liverpool Medical Institution, on February 20th, Dr. O. L. V. DE WESSELOW read a paper on renal oedema. Discussing the various renal lesions with which oedema was associated, he pointed out that very gross pathological changes in the kidney might be associated with satisfactory excretion of water, and that in types of renal disease in which oedema appeared the only common factors seemed to be a high percentage of protein in the urine and a diminution in the excretion of water, the oliguria not necessarily being attributable to renal damage.

Reviewing the "retention" or purely renal theories of this type of oedema, Dr. de Wesselow suggested that the phenomena of renal dropsy were as readily explained by pre-renal deviation of water to the tissues as by failure of the kidney to excrete water. The blood volume in nephritic oedema was not suggestive of retention of water owing to renal failure. For Widal's salt retention theory due to renal failure to excrete chloride little could be said. It had been shown by Lundin and Scharf that in partially nephrectomized animals salt feeding led to enormous salt retention, but that such salt retention was dry and was not accompanied by water retention. The interesting theories of Epstein and Kylin might present a more exact picture of the processes underlying the development of renal oedema. The hypalbuminosis of the blood plasma, which had been considered by Epstein to be the cause of renal oedema, might, however, persist after the oedema had cleared. The increased permeability of the capillary wall, advocated by Kylin, needed further proof. The whole question might be clarified in the future by separate consideration of the oedema of glomerulo-nephritis and of nephrosis. Though both types of oedema happened to be associated with albuminuria, their causation need not be identical, and there seemed to be good reason for assuming that they were separate entities.

SYMMETRICAL NECROSIS OF THE RENAL CORTEX.

AT a meeting of the Edinburgh Obstetrical Society on February 12th, Drs. TURNER and J. DAVIDSON presented a paper on symmetrical necrosis of the renal cortex, which was illustrated by a clinical record of two cases occurring in Dr. Turner's practice. From a study of these cases certain points of similarity with regard to symptomatology, or rather the lack of it, were pointed out.

Both patients were multiparae, one being a 4-para and the other a 3-para; their respective ages were 37 and 33. Both were delivered of macerated foetuses at the seventh month of pregnancy. In the first case there was an antecedent history of pre-eclamptic toxaemia and accidental haemorrhage, but in the second case no abnormality during the ante-natal period was present. Both patients lived for twelve days after delivery, during which time marked diminution in the urinary secretion was present, 19 ounces being passed by the first, and 8 ounces by the second. In both there was a comparative absence of symptoms. Until the eighth and fifth days respect[illegible] features were partial suppression of urine [illegible] generalized oedema. The puerperia were [illegible] the eighth and fifth days uraemic phenomena began to appear, but were slight in degree; they consisted, first, of progressive drowsiness, stupor, and ultimately of coma, secondly of dyspnoea, and thirdly (in the first case) of uraemic vomiting. In both death supervened in the absence of convulsions. Treatment in both cases was on general lines, including free elimination, diaphoresis, and the administration of diuretics, but without benefit.

In both cases the kidneys showed the same characteristics—namely, total necrosis of the outer two-thirds of the cortex, the inner third being healthy; there was slight congestion of the medullary portion. In neither case was there thrombosis of the renal vessels, nor was there any evidence of previous nephritis.

In the first case the liver presented areas of focal necrosis of the central zone cells of the lobules.

Dr. Davidson showed specimens of kidneys from three cases of bilateral cortical necrosis of the kidneys, one relating to a case that had already been described by Dr. Turner. The second case showed the earliest changes of this condition; thrombosis of the afferent arterioles of the glomeruli was well seen in microscopic sections. The third case displayed advanced stages of necrosis, and was of interest because there was ante-mortem thrombus formation in both ovarian veins. Dr. Davidson pointed out that there had been one case previously described in literature where thrombosis, visible to the naked eye, had occurred in both renal and ovarian veins. The pathology of the condition was discussed, and lantern slides were shown illustrating the well-marked primary arterial thrombosis of the inter-lobular arteries which was due primarily to the deposition of blood platelets. Attention was also drawn to a case which was published some years ago of a man, aged 37, whose kidneys showed the typical appearance of bilateral cortical necrosis.

LEUCOSARCOMATOSIS.

A MEETING of the Section of Pathology of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on February 21st, with the president, Dr. J. LAIT, in the chair; Dr. H. F. MACAULEY reported a case of leucosarcomatosis in a boy aged 21 months.

Dr. Macauley said that the patient had been quite healthy till three weeks before admission to hospital, when he began to suffer from gastric trouble which gradually got worse; he then developed periorbital swelling with haemorrhagic staining of the overlying skin. On admission to hospital it was found in addition that the abdomen was considerably distended, and a definitely enlarged liver extending to the umbilicus could be felt, with enlargement of the spleen and right kidney as well. Blood examination showed a condition of lymphocytic leukaemia. Progress of the malady was rapid, death occurring within five weeks of the onset.

Dr. W. D. O'KELLY demonstrating a kidney from the case, said that the cells which had invaded the kidney, though varying somewhat in type, were chiefly mononuclears. The difficulty about cases such as this was the nomenclature; he thought that the proper name was leukaemia with tumour formation, for examination of the blood left no doubt that leukaemia was present.

The PRESIDENT mentioned two cases seen recently which resembled this case. The first patient, a boy aged 3, had had his tonsils removed, and returned to hospital about three weeks later with enlarged glands in the neck. General glandular enlargement was found, and lymphatic leukaemia was diagnosed by blood examination; a very large number of nucleated red cells was present. The child died of haemoptysis, and at the necropsy a large tumour in the mediastinum was found, which had apparently started in the thymus. The second patient was a man with pyrexia who had been treated at first as a case of pneumonia, but after ten days a big tumour was found to be the cause of the consolidation of the lung. He also suffered from leukaemia, and died quickly, but a post-mortem examination was not permitted. In cases in which there was leukaemia and tumours, it was difficult to decide the exact relationship of the two.

Dr. P. J. SHANLEY said he had seen the case with Dr. Macauley; a blood film supported the clinical appearance of classical chloroma. Dr. T. T. O'FARRELL mentioned a case he had seen which was similar, being a typical one of chronic lymphatic leukaemia. The condition of the patient's face resembled that in leprosy. The patient died, and at the post-mortem examination most extensive glandular enlargement was found.

Cerebral Abscess of Unusual Etiology.

Dr. T. G. WILSON described the clinical features of an abscess of the temporal lobe of the brain, which occurred in a child aged 6. The patient had very few symptoms, and a simple mastoidectomy was first performed; this operation revealed some necrosis of bone around the mastoid antrum, but the dura of the middle fossa was normal on exposure. Nine days later, however, the patient's condition was not satisfactory, and a radical mastoidectomy was performed. At this operation a fistula was found leading through the tegmen tympani into the temporal lobe of the brain, and about 3 c.cm. of fetid creamy pus was evacuated from a brain abscess through it; a Gram-negative bacillus was found in pure culture in this pus, and was isolated from the cerebro-spinal fluid. The child developed purulent meningitis five days later and died.

Professor J. W. BIGGER said the organism belonged to the pseudomonas group. It was Gram-negative; produced a brownish pigment which diffused through solid medium; was actively motile; and failed to ferment any sugar or to produce indol. The cerebro-spinal fluid was very cloudy owing to the large number of organisms present and in spite of the almost complete absence of pus cells. The organism was one of a very low degree of pathogenicity.

Mucoid Carcinoma of the Breast.

Dr. T. T. O'FARRELL exhibited a specimen of mucoid carcinoma of the breast which had been removed from a woman aged 65. On admission to hospital the tumour was found to be freely movable, with no involvement of the skin or nipple, and no glandular enlargement. Under the impression that the growth was benign a limited removal was contemplated, but, as the specimen presented a doubtful appearance when incised, a radical operation was performed. The patient made an uneventful recovery and left hospital in nine days. The growth measured 3 by 2.5 by 3 cm., being more or less spheroidal. On section it had a gelatinous appearance, with some points of haemorrhage; in places the tissue was more solid, and was closely adherent to the surrounding fat. Microscopically the specimen presented the appearance of mucoid carcinoma. It consisted of islands of spheroidal epithelium imbedded in mucoid material, which gave the typical reaction with haematoxylin. There was an occasional attempt at acinus formation, but this was exceptional. Very few mitotic figures were observed.

Empyema due to Gaertner's Bacillus.

Dr. R. H. MICKS and Dr. G. C. DOCKERAY made a communication on a case of empyema due to *B. enteritidis* Gaertner. An infant, 16 months old, was admitted to hospital suffering from pneumonia; within a few days of admission, and when the pneumonia fever had begun to decline, extensive pleurisy appeared at the base of the right lung. An effusion developed, which was drained by rib resection; it was fibrino-purulent, solid fibrin forming the greater part of the contents of the pleural cavity and fluid pus being relatively scanty. Uninterrupted recovery followed. The organism, obtained in pure culture from the effusion and seen in large numbers in stained films, was identified by Dr. Dockeray with the *B. enteritidis* Gaertner; the patient's serum after operation contained no agglutinins for the organism isolated, a feature not unusual in Gaertner infections. The stools were plated on two occasions, but no organism resembling *B. enteritidis* was found, and no explanation of the infection was forthcoming; search through the literature on the subject led to the belief that this was the first case recorded of empyema due to Gaertner's bacillus.

Dr. DOCKERAY, describing the bacillus which he had isolated from the case, stated that it was typical in so far as its microscopical and biochemical behaviour was concerned. In spite of the fact that it agglutinated with Gaertner serum to full titre, it would be necessary to await the results of agglutinin absorption tests in order to determine whether it really was *B. enteritidis*, or some very closely related serological type, such as the Dublin or Tokio strains.

Reviews.

A SYSTEM OF BACTERIOLOGY.

IT will be remembered that towards the end of last year volume iii of the *System of Bacteriology*[1] was reviewed in these columns (November 16th, 1929, p. 903). Volume ii,[1] the third to appear, is devoted to a consideration of the cocci and haemophilic bacteria. Both these groups of organisms are of outstanding importance, the former because it comprises the agents of so many common diseases of man, the latter because its consideration entails a review of that vexed question the etiology of influenza. We looked forward, therefore, to some interesting reading in this volume, and it may be said that in the main this anticipation is realized.

The volume opens with an account of the staphylococci by A. Fleming. Most bacteriologists would probably admit that, despite the importance of this organism to both surgery and medicine, they look upon its study as a somewhat dull occupation. One has the feeling that the author has approached his task in some such spirit; the account is orthodox and correct, but it is unlikely to arouse interest. Chapter II, which is devoted to the streptococci, and is contributed to by a number of authors (J. W. McLeod, T. J. Mackie, D. G. S. Percival, and C. H. Browning), is excellent. Space forbids a detailed analysis of this chapter, and where so even a standard is maintained it might be thought invidious to single out a few features for comment. Such questions, however, as the rôle of the haemolytic streptococcus in the etiology of scarlet fever, the relation of streptococci to rheumatic fever, and subacute bacterial endocarditis, call for special mention. They are questions of particular importance, and their treatment is critical and exceedingly well balanced. The next chapter on the pneumococcus, by W. Mair, J. W. McLeod, and F. Griffith, is equally good, and the account of the serological races of this organism most interesting, especially Griffith's experiments on mutation of types. Following this we have accounts of the meningococcus and the gonococcus, by E. C. D. Murray and W. J. Tulloch respectively. Both writers have given clear and eminently readable accounts of their subject, in which possible lines of future research are not obscured by a recital of what is already known.

Perhaps the best of the many good chapters in this volume is that on the influenza group of bacteria, by W. M. Scott. Here only the true haemoglobinophilic bacteria are dealt with, organisms such as *B. pertussis*, *B. ducreyii*, and *B. lacunatus*, included in the haemoglobinophilic group in the American classification, being relegated to a separate chapter of their own, for the good reason that they can be grown in media devoid of blood. The feature of the account of the influenza group is the discussion of the problem of the etiology of influenza, which is a really masterly appreciation of the situation. It should serve as a most useful baseline from which to start further research. This chapter has in addition a section on *B. pneumosintes*, contributed by McCartney, in which the claims of this organism to be the etiological agent of influenza are considered in a clear and unbiased manner. The volume closes with a chapter on *B. pertussis*, *B. ducreyii*, and *B. lacunatus*, by R. T. Hewlett, which is clear and adequate.

SPINAL ANAESTHESIA.

THE original purpose with which Dr. CHARLES H. EVANS wrote his monograph on *Spinal Anesthesia*[2] was to provide a textbook for use in the New York Post-Graduate Hospital. While claiming no very great originality either in methods of technique of spinal anaesthesia or in the choice of the drugs used, the author believes that the technique advocated and the drugs described provide adequate anaesthesia for the surgeon to carry out his work

[1] *A System of Bacteriology in Relation to Medicine.* Medical Research Council. Vol. ii. London: H.M. Stationery Office. 1929. (Sup. roy. 8vo, pp. 425. Single volumes £1 1s. net; set of nine volumes £8 8s. net.)

[2] *Spinal Anesthesia.* By Charles H. Evans, M.D. Introduction by W. Wayne Babcock, M.D., F.A.C.S. Foreword by Charles Gordon Heyd, M.D., F.A.C.S. London: W. Heinemann (Medical Books) Ltd. 1929. (6 × 9½, pp. xxii + 203; 40 figures. 25s. net.)

and a proper degree of safety for the patient. Dr. Evans does not disdain the use of supplementary general anaesthesia, and so his outlook on the matter is wide. He is very insistent on the proper choice of the patient who is to be submitted to spinal anaesthesia, and he is broadminded enough to agree that there are variations in the technique described by him which give good results in the hands of skilled administrators. This monograph is not intended for the latter, but for the beginner who wishes to learn methods which are simple and tolerably safe.

Dr. Evans's descriptions are clear and his teaching sound, and the monograph can be recommended to those who wish to undertake operative work under spinal anaesthesia. The illustrations are for the most part excellent, but it is a pity that some of the rough diagrams should not have been handed over to an artist to finish, to bring them up to the level of the less diagrammatic illustrations. By this we do not mean that clarity should be sacrificed to artistic detail. Diagrams can be constructed to look neat and tidy, which is not the case with all those here collected; for some look distinctly smudgy and spoil the effect of a work on which the publisher has obviously spared no pains, since the get-up of the book is excellent as regards type and the majority of its illustrations. Apart from these few blemishes the monograph is excellent, and written, moreover, in a manner that is extremely readable.

AN INTRODUCTION TO THE STUDY OF THE NERVOUS SYSTEM.

To write a book for students is often more difficult than writing for the adept, and to write a short book for those who have most to learn is one of the hardest of educational tasks. Dr. HEWER and Dr. SANDES have attempted this in their *Introduction to the Study of the Nervous System*,[3] which is designed to convey, especially to the student, the essentials of neurological anatomy and physiology. Much of the book attains a high standard. The anatomical sections are well done, and the coloured diagrams for the most part are clear and well arranged, though diagram 29, designed to show the innervation of the salivary and lacrymal glands, is, perhaps inevitably, somewhat reminiscent of a map of the Underground railways. Certain defects, however, must be noted. The presence of sensory fibres in the anterior limb of the capsule (diagram 13) is not generally recognized, but this may be a colour misprint. The charts designed to demonstrate visual field defects are unsatisfactory, since there are two visual fields, and not one, and the student will not derive a clear idea of the meaning of homonymous hemianopia, for example, from the diagrammatic method employed. The physiological sections, especially those with[illegible]t reach the standard of the l[illegible]tomy. The criticism, if not the [illegible]neurologist would enhance the value of subsequent editions.

HYDROGEN-ION CONCENTRATION.

BIOCHEMISTRY has, by right of use, established a proprietary interest in the concept of "hydrogen-ion concentration." The control of the hydrogen-ion concentration—the *p*H—has become one of the commonest of routine observations in biochemical laboratories. It is probable, therefore, that biochemists and physiologists will be attracted by Dr. H. T. S. BRITTON's work, entitled *Hydrogen Ions*,[4] the third volume in a series of monographs on applied chemistry published under the editorship of Dr. E. Howard Tripp.

Dr. Britton's monograph is valuable, though it does not touch directly upon many problems of general biological interest. It gives in detail the acceptable methods for the determination of hydrogen-ion concentration. The wealth of technical detail will be of great service to the laboratory worker. Thereafter, the book is given over to a survey of the value of *p*H measurements in the practical control of a wide field of applied chemical processes. Few of these applications are of direct biological importance, the interest of the author being rather in the field of industrial chemistry. Brewing, baking, milk and water supply, sewage disposal, the tanning of leathers, the paper, pulp, sugar, textile, and dye industries, ceramics, and the electrodeposition of metals—all these are dealt with in greater or lesser detail, according to the amount of available data. The biochemist will probably close the book with the satisfactory reflection that other branches of applied chemistry have been much more dilatory than his own in the practice of hydrogen-ion control. Nevertheless he can profit by perusing their studies.

It is not always realized that *p*H is something more than a logarithmic scale on which are compared observations made with the aid of certain technical methods. It is also a symbol for an important theoretical abstraction—the acid-base affinity of a system. This aspect of its proper use is becoming of increasing importance. Dr. Britton, however, offers no service to the student of the theoretical problem. His object is to describe a technical weapon and to illustrate its usefulness. This he has done well. Within its prescribed field the book is a good example of what a monograph should be.

MAN AND CIVILIZATION.

Of recent years there have been published, particularly in the United States of America, a considerable number of books, some by a single author, others by many authors under a common editorship, purporting to give a comprehensive survey of Western civilization and of the development of those essential features of the human body and mind which have enabled it to come into existence. The time has probably arrived when a pause in the production of works of this kind is desirable, as most of these publications contain valuable features, and as, between them, the ground has been abundantly covered. A third and revised edition of one of them, however, may be welcomed as showing that it has at any rate survived some tests of value. This is *Man and Civilization*[5] by JOHN STORCK, instructor in philosophy in Columbia University. Its subtitle is "An Inquiry into the Bases of Contemporary Life," and its object is described as being "to enable the ordinary educated reader to realize what might be called his place in the scheme of things." It is rather long, not so much by reason of its number of pages as because it is packed full of matter. It is an effective attempt to analyse comprehensively that combination of biological, psychological, and sociological conditions under which man now lives in civilized communities, and the way in which these conditions have survived and been developed during the unfailing continuity of life. It is not a book that can easily be read through uninterruptedly, but rather one to be intimately studied during a college or university course. The preface, indeed, states that "preliminary editions were used as required reading in the prescribed freshman course in contemporary civilization which is given in Columbia College." The book is divided into four parts, entitled: "The world we live in," "How we come to be what we are," "Human nature and social complexes," and "Contemporary ways of life." These titles do not, perhaps, of themselves indicate the nature of the contents. The analysis begins by tracing the consequences of the fact that man is a biological organism developing and existing in close dependence on a culture pattern. The essential features of that culture system, known as Western civilization, are described in their relation to other cultures. The ways in which this system leads the individual members of the group to fall into its characteristic routines, to speak its language, to use its tools, machines and techniques, and to accept its values are then traced. Finally, there is an examination of the place of economics, of the family, of art, of science, and of religion in this modern civilized life. No part of the book is inadequate for its purpose, and there are several sections which are especially valuable and suggestive. For instance,

[3] *An Introduction to the Study of the Nervous System.* By E. E. Hewer, D.Sc.Lond., and G. M. Sandes, M.B., B.S.Lond., etc. London: W. Heinemann (Medical Books) Ltd. 1929. (Cr. 4to, pp. xii+191; 55 diagrams. 21s. net.)

[4] *Hydrogen Ions.* By Hubert T. S. Britton, D.Sc.Lond., B.Sc.Bristol, D.I.C., F.I.C. Monographs on Applied Chemistry. London: Chapman and Hall, Ltd. 1929. (Demy 8vo, pp. xiv + 515; 103 figures. 25s. net.)

[5] *Man and Civilization.* By John Storck. Third, revised edition. London: Constable and Co., Ltd. 1929. (Demy 8vo, pp. v + 449; illustrated. 15s. net.)

we may mention the summary survey of contemporary economic life in Chapter XIV and the study of methods of thinking in Chapter VII on "the organization of the intellectual life." Those who agree that "the proper study of mankind is man," and that to know themselves and get along with one another is the most important business of human beings, will find in Mr. Storck's book much material for such study and, it may be also, practical help in that business.

NOTES ON BOOKS.

THE handy volume on *General Medicine*[6] in the Practical Medicine Series (1929) consists of five parts devoted respectively to infectious diseases, diseases of the chest, excepting the heart but including tuberculosis, diseases of the blood and kidneys, diseases of the heart and blood vessels, and diseases of the digestive system and metabolism. In the section on infectious diseases, compiled by Dr. George H. Weaver, assisted by Dr. T. T. Crooks, undulant fever and tularaemia take precedence of all the other diseases, which include *influenza, malaria, the acute exanthemata, epidemic diseases* of the nervous system, mumps, and enteritis. In the section on diseases of the chest Dr. Lawrason Brown draws attention to the increase of pulmonary embolism and of primary tumours of the lung, and reviews recent literature on the B.C.G. vaccine, among other subjects. Dr. George R. Minot and Dr. William B. Castle devote special attention to the treatment of pernicious anaemia and the experimental production and nature of nephritis. In the section on diseases of the heart and blood vessels Dr. William D. Stroud reviews recent work on rheumatic cardio-vascular disease, angina pectoris, and blood pressure. Dr. Ralph C. Brown deals with recent advances in the treatment of gastric diseases, peptic ulcer, duodenal stasis, the diagnosis of gall-stones, the varieties of jaundice, diverticulitis, diabetes, and exophthalmic goitre.

In issuing the forty-sixth annual volume of *The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland*[7] the publishers announce that this volume will probably be the last to be published in the more complete form, as the special appeal that was made to societies to order the book has not been successful. If further support is not forthcoming the lists of papers printed in future will be confined to those that are also published. This would be an unfortunate restriction, as the *Year-Book* is a reliable and comprehensive guide to the work of numerous societies and Government institutions. The present issue, which refers to work done in science, literature, and art during the session 1928–29, follows the general arrangement of its predecessor. In the section on medicine there are lists of reports, publications, and papers of the Ministry of Health, the British Medical Association, the Royal Society of Medicine, the Medical Research Council, and of other medical bodies.

A second edition of Professor JAMES SMALL'S *Textbook of Botany*[8] which is designed for medical and pharmaceutical students, has been published. The short accounts of carbon assimilation and geotropism have been brought up to date, and certain subjects have been treated more fully.

The second volume of *An Introduction to the Chemistry of Plant Products*,[9] by Dr. P. HAAS and Professor T. G. HILL, has the subtitle of "Metabolic processes"; its predecessor was noticed in our columns of November 17th, 1928 (p. 901). This new volume will be found of great interest by all who are interested directly or indirectly in biochemistry. The early chapters deal with the synthesis of carbohydrates, fats, and proteins by plants. Chief attention naturally is devoted to the first of these processes, for upon this depends the ultimate supply of energy for all living processes, both in plants and animals. The middle third of the book is devoted to respiration, and the last third to growth. At the end of the last chapter certain problems are discussed which have a bearing not only on plant but also on animal physiology. The importance in nutrition of traces of various inorganic elements is a problem that is easier to investigate in plants than in animals, and it is interesting to learn that traces of boron and of manganese are essential for the growth of many plants. Traces of zinc act as stimulants to the growth of moulds. From this subject the authors pass to a discussion of the presence of hormones in plants. Here, however, the evidence is much more obscure in vegetable than in animal physiology. This volume, apart from its value to botanical students, will also be of great use to those who are primarily interested in animal physiology, but wish to find a short account of the present state of knowledge in plant physiology on subjects where the two branches of physiology have a common interest.

PREPARATIONS AND APPLIANCES.

AN AID TO OPERATIONS ON INFANTS.

MR. DENIS BROWNE, F.R.C.S. (Surgeon to the Hospital for Sick Children, Great Ormond Street), writes: In operating on babies there are certain special difficulties. Owing to their light weight and powers of contortions they need careful holding for greater or less time, according to the type of anaesthetic, and their small size makes it difficult for the holder to avoid the operators. They are very sensitive to overdoses of ether or chloroform, especially when they are toxic or starved, and their relatively large surface area and defective heat-regulating mechanism make them particularly liable to chills during operation.

In work on these cases, both as operator and as anaesthetist, I have found great help in a simple device, which holds the child firmly, prevents chilling, and permits the use of local anaesthesia, or the minimum of general. It is a "crucifix," the original model of which was a simple T of 2-inch wood, the cross limb 18 inches long, and the main one 24 inches. As this was awkward to carry, and had an inauspicious look about it when taken into a private house, I got Messrs. Allen and Hanburys Ltd. to make me a collapsible model in duralumin, with a sponge rubber padding, and this has been very satisfactory. The baby is wrapped in warm cotton-wool over as much of its body as possible, according to the operation to be done, and bandaged firmly to the frame, on which subcutaneous saline or artificial respiration can be given without removing it.

Incidentally it is interesting to see how often a baby that has been restlessly wriggling and crying will settle down and go to sleep as soon as it is firmly fixed. It suggests that possibly there were advantages, at any rate to the parents, in the tight swaddlings which so many nations used for so many ages.

ELIXIR IODO-CREOSOTI CO.

Elixir iodo-creosoti co. (Wyleys Ltd., Coventry) is a mixture containing creosote, potassium iodide, and caffeine sodio-salicylate, together with various other vegetable drugs. The compound is suitable for use in pulmonary infections accompanied by rise of temperature.

THE HUMAN BRAIN.

LECTURE BY PROFESSOR ELLIOT SMITH.

THE human brain was the subject of a lecture delivered by Professor G. ELLIOT SMITH at the Royal Society of Arts, under the presidency of Sir OLIVER LODGE, on March 12th.

The lecturer addressed himself particularly to the question of such characteristics of the human brain as may be supposed to differentiate man in the quality and range of his intellect from all other living creatures. From the time of the Greeks onwards, he said, men had been speculating as to the nature of the human intellect, but serious investigation of the brain dated back to not much more than a century ago, when Franz Joseph Gall, whose name was associated with what afterwards became known as phrenology, obtained his real renown by destroying the old traditions regarding the nature and functions of the brain and starting modern research on proper lines. Up to Gall's time the leading authorities on the anatomy and physiology of the brain had seriously believed that the important thing was the cerebral fluid, and that the brain structure was a mere organism for secreting it. Gall pricked that absurd bubble, and his work was the starting-point of an intelligent attempt to interpret the comparative anatomy of the brain. The experiments of Flourens, the famous French physiologist, suggesting that the stimulation of the brain afforded no indication at all of any localization of function, and that very much the same results occurred whatever the stimuli, were also of interest. The search for some distinctive feature of the human brain to account for the mental superiority of man occupied comparative anatomists for a long period, and acute controversy arose out of these attempts. Professor Elliot Smith referred to the lively debates which ensued upon the theory that the longitudinal eminence on the floor of the posterior horn of the left ventricle of the brain, expressing the projection into the ventricle of the calcarine sulcus, was peculiar to man. This view figured in the controversy in which Owen and Huxley were engaged in the sixties, a controversy on which Kingsley's *The Water Babies* was a skit. It was presently proved, however, that this feature was not peculiar to man, and although different anatomists had at various times set up other criteria as structural distinctions of the human brain, every one of them had in turn been shown to be false. There was no structural feature of the human brain which was not also present in the brain of the higher apes, and it was impossible to take out any particular feature and say that upon this character the intellectual superiority of mankind depended.

Professor Elliot Smith then proceeded, with the aid of a long series of lantern slides, to make clear his argument that the growth of the brain and the mind was the result of the change of increasing complexity of habit and of motion, which lay at the bottom of all evolution, that the growth of structure depended upon function, and that with greater range and complexity of function came elaboration of structure.

Professor E. W. MACBRIDE, in some observations following the lecture, recalled Bergson's remark that the human reason was a "food-getting mechanism." If one could imagine a superior being visiting this sublunary sphere and watching evolution, said Professor Macbride, he would come to the same conclusion as he saw the growth of the great central ganglion going on step by step with the increasing complexity of the habits of the animal. It was Bergson's view that the characteristic of the human reason to find a materialistic explanation of every occurrence was due to the fact that since the reason was evolved to deal with material objects, from the early flint and stones, it had an inborn tendency to resort to such a method of explanation.

Sir OLIVER LODGE, from the chair, said that he supposed no one would now go so far as to regard the brain and the mind as synonymous. The brain was the organ of the mind in the same way as the violin was the instrument of music. The brain itself could not be conceived as thinking, planning, hoping, or loving, though he admitted that all those things in our present existence could not be accomplished without a physical concomitant. The important thing, in Sir Oliver Lodge's view, was not matter, which as modern physics had shown was but a small portion of the whole, but the spiritual entity (as he viewed it) surrounding matter, in its interstices, in the space between atoms or between worlds, which entity might well have vital functions to perform.

THE DOCTOR IN THE LAW COURTS.

A JOINT DEBATE.

THE Medico-Legal Society and the West-London Medico-Chirurgical Society held a joint discussion on March 7th on "The doctor in the law courts."

Sir WILLIAM WILLCOX said that the doctor regarded the law courts with aversion; they were time-consuming, and cross-examination was apt to be unpleasant. The Medico-Legal Society had done something to remove this natural repugnance, for in that body the lion—who were, of course, the lawyers—lay down with the lambs, who were the other party to the combination. Sir William thought it important for doctors in their practice to cultivate what he called the medico-legal atmosphere. They must bear in mind that many members of the public had a natural love of litigation, and that statements made casually to a patient or to a patient's friends might have consequences in the courts. He recalled a case in which a man who was really suffering from commencing pemphigus vegetans consulted a doctor for an ulcer in his mouth. The doctor inquired as to his tooth-paste, and, on being told, said "Carbolic burn," whereupon the patient commenced a legal action against the proprietors of the dentifrice. The action, of course, went no further when it was discovered that the mouth condition was due to bullae of pemphigus.

One of the most honourable functions of the practitioner (Sir William Willcox continued) was the giving of evidence. It was worth while remembering, however, that when a subpoena was served conduct money should be paid. He recalled an occasion when, working among his out-patients one morning, a well-dressed gentleman entered whom he at first took to be a foreign doctor. He got up to shake hands with him, and the visitor pressed into his palm a guinea and a piece of paper—a subpoena to attend a compensation case which necessitated his spending several days at Aylesbury. The privilege of giving evidence carried with it no small responsibility, and might affect not only the persons involved in the action, but the doctor's own reputation. Evidence might be either of fact or of opinion; evidence of opinion was of the nature of expert testimony. Every medical man who went into the witness-box might be, and generally was, asked for his opinion. He should be very cautious in uttering opinions unless he was certain of his ground. The speaker recalled an incident in the Hadwen trial at Gloucester in 1924, when a medical witness was asked by the late Sir E. Marshall-Hall to give his opinion as regards statistics of death from diphtheria before the use of antitoxin. He replied, quite properly, that he would prefer not to answer the question as it was not his special department, and in that attitude he was supported by the judge. The language used in giving evidence as to fact should be such as was understood by persons of average intelligence possessing no special knowledge. It was better to say "nose-bleeding" than "epistaxis." Facts should be clearly and concisely stated, and comments avoided. The function of the expert witness was to assist the court by his special knowledge and experience; he should not regard himself as an *ex parte* witness. The giving of expert evidence was a responsibility not to be lightly undertaken. The statements of fact on which the inquiry was based should be carefully studied and examined in a critical spirit. The witness should refresh his mind by a careful study of recent scientific research relating to the subject, and if in doubt he should, if possible, verify by

experiment on any point. He should unsparingly cross-examine himself on every aspect of the question. He must have regard to the point of view of the judge and of the cross-examining counsel as well as to that of the counsel on whose side he happened to be. The success of an expert witness was much assisted by an appreciation of the attitude of mind of those who questioned him, and he was thus able to anticipate questions, and to meet with tolerance and charity questions which might otherwise annoy him. The witness should be careful never to put down anything in a medical report which he could not substantiate in the box. In a big case there might be half a dozen doctors on each side. Sir William Willcox thought it desirable that the several medical men on one side who were going to give evidence should confer together, not at all with the idea of getting any one of them to change his evidence, but in order to rule out irrelevancies, clear up doubtful points, and see what agreement existed. In examination and cross-examination answers should be as clear and concise as possible. Lengthy explanations and evasions of a direct answer created a bad impression. The direct affirmative or negative should be given wherever possible, and if not possible the reason for inability to give it should be shortly stated. Attempts to give lectures in the witness-box were likely to weaken confidence and to raise points of which the cross-examining counsel would take advantage. Witnesses should avoid making any statement which was not an answer to a question put. If a question was a double or triple one they should ask that it be divided. Quotations from books or reports put to the witness should be accepted with caution; it was well to ask to see the book or report.

Sir William Willcox concluded with some remarks on coroners' courts, where the rules of evidence were not strictly followed, and hearsay evidence not ruled out. Some recent criticism of coroners in connexion with two prolonged inquiries was not quite just, because on the coroner in both these cases depended the whole responsibility, the Crown having instituted no prosecution. By the present procedure, if a criminal prosecution was started, the coroner's inquiry was postponed until the result of the prosecution was forthcoming.

Lord RIDDELL spoke on medical privilege. Many doctors, he said, resented the fact that the same privilege was not given to the medical as was given to the legal profession. Such resentment grew out of a misunderstanding of the nature of legal privilege. Lawyers were not entitled to privilege at all; the privilege was that of their clients, with whom it rested to say what lawyers should and should not divulge; though even this right of the client was of a limited character, for the law did not permit solicitors and barristers to enable criminals to escape—"except through the ordinary processes of law"! There was one absolute privilege for witnesses, and that arose in a case in which a doctor was concerned. This doctor, in the witness-box, had made statements reflecting on a third party. Action was brought against him for slander, and the plaintiff in the first court recovered £50, but on the matter being taken to appeal it was laid down absolutely that any witness could say what he liked in the witness-box, whether his statements were pertinent to the case or not. The expert medical witness was a comparatively modern innovation. The first such witness appeared in the case of Miss Blandy, who was tried (and hanged) in 1752 for poisoning her father. The expert witness in that case was Dr. Adlington. One of the advantages of the medical witness was that, being an expert, he was permitted to express an opinion, while most witnesses could only deal with facts. The legal maxim was, "Who is skilled in his profession is to be believed," which was rather open to question. Lord Riddell concluded with some sound advice to the witness, not to be testy, not to appear conceited or vain, to look simple while being wise, and to take urbanity as the most effective shield.

Sir WILLIAM COLLINS said that medicine was not an exact science: it was rich in hypotheses, it could not point to many general laws, nor premise with certainty on the matters with which it was dealing; it did not lend itself very readily to precise legislation. But law, handed down from precedent to precedent or embodied in statute, was more or less an exact science. Therefore the medical witness when he went into the box was apt to be confounded with the old fallacies, the fallacy of many questions, the fallacy of *Petitio principii*, and the fallacy of *Circulus in probando*, so that when he left the witness-box he was likely to make the reflection attributed to John Hunter—that definition was of all things most damnable. With regard to coroners' courts, he recalled a time when coroners were neither doctors nor lawyers. When he was chairman of the Public Control Committee of the London County Council he endeavoured to secure that in future coroners should be qualified in both medicine and law, and this was now the case, at any rate in the county of London.

Dr. F. TEMPLE GREY referred to Lord Birkenhead's essay on "Should a doctor tell?" which was not very flattering to the profession, but contained some truths of which the profession should take note. The British Medical Association would be doing good service if, in co-operation with the Medico-Legal Society, it formed a strong committee to devise a code of conduct in such matters for the help particularly of the younger members of the profession.

Mr. MCADAM ECCLES spoke of the difficulty, when giving an expert medical opinion, of answering "Yes" or "No" while yet sticking to the whole truth and nothing but the truth. On several occasions under this line of questioning he had turned to the judge and said, "My lord, I have sworn to tell the truth, the whole truth, and nothing but the truth, and I cannot do that by answering 'Yes' or 'No,'" and the judge had always upheld him. Members of the medical profession were not partisans on either side, and if a professional man went into the box with the intention of giving evidence purely on one side he was not an expert witness. Mr. Eccles had a "bone to pick" with the courts—namely, that they tended to look upon all registered medical practitioners as possessing an equal degree of knowledge in all branches of medicine and surgery, with the result that sometimes a surgeon, who had been preceded in the box by another medical man without his special knowledge of, say, anatomy, was confronted with an opinion which had just been delivered by his confrere and asked how he could disagree with it. The most highly qualified medical man, while of great service as an expert witness in one particular line, ought not to be regarded as speaking with equal authority on some quite different line. He thought there ought to be an opportunity for medical men on both sides to confer with the medical assessor or referee, and when he had asked for that it had never been refused. Indeed, on more than one occasion the judge had said, "May I come in also?"

Dr. KNYVETT GORDON said that no pathologist should give any opinion in the witness-box as to the significance of his tests on a given patient without himself having seen the patient. There was some tendency to substitute pathological tests for clinical opinion. The error with the Wassermann test as indicative of syphilis was about 15 or 20 per cent., but even if it was much less than this, if there was any error at all, the pathologist, when asked what was the significance of the Wassermann reaction in a particular case, must say, "I do not know," or possibly state what was the margin of error.

Dr. JULIUS BURNFORD expressed some disappointment with the course of the discussion. He had hoped that the fundamentals of the question would be attacked—namely, the whole position of the medical witness in the law court as it existed at present, as to whether it was a right position, or the best from the point of view of justice, and whether it was possible for medical men to appear on opposite sides, in either civil or criminal cases, and tell the truth, the whole truth, and nothing but the truth. Many years ago Sir Clifford Allbutt, when in Leeds together with his colleagues in that town, refused to go into the witness-box without a preliminary consultation with the medical men in the case, and apparently this method served the interests of justice, although (according to a letter by Allbutt in the *British Medical Journal* in 1880) it met with opposition from the lawyers—open foes the solicitors, covert from the bar—because it tended to cut down their fees.

British Medical Journal.

SATURDAY, MARCH 22ND, 1930.

THE FEMALE SEX HORMONES.

RECENT work on the mechanism of the oestrous cycle and the regulation of ovarian periodicity has revealed in rats and other mammals the existence of an extremely complex hormonal system in which at least four internal secretions are concerned—two produced in the ovary and two in the anterior portion of the pituitary body. As far back as 1906 Marshall and Jolly[1] produced the phenomena of œstrus in the anœstrous bitch by means of an ovarian extract, subsequent work leading to the isolation of the hormone, appropriately named oestrin (Parkes), which appears to be directly responsible for producing the vaginal changes in the œstrual cycle of the rat and mouse. Later investigation has demonstrated the production in the corpus luteum of an oestrus-inhibiting hormone; and from extracts of the anterior lobe of the pituitary body have been separated an oestrogenic hormone which induces premature development of puberty in mice and rats, apparently by accelerating the maturation of the ovary, and an oestrus-inhibiting hormone which produces its effect by stimulating the development of lutein tissue. Yet other hormones regulating the female reproductive system have been postulated, but for the existence of those mentioned the body of experimental evidence is now so overwhelming that only the details of their physiological action and interrelations remain to be worked out in the laboratory.

The clinical application of these discoveries is as yet in its infancy, for although the use of ovarian extracts, above all of oestrin, is widespread, there has been but little orderly research into their action. It is probable that the discouraging results so far obtained may be attributed not to the fact that these hormones, so important in animals with a biphasic sexual cycle, are unimportant in the human subject, but to the uncertain dosage of the preparations available and the great cost of extracts having a sufficient activity. Thus Shaw,[2] who from the administration of oestrin obtained what he believed to be definite clinical improvement in a number of cases, recommends as a minimum dose about 50 rat units. Probably little of the available commercial material reaches this standard of biological activity, and it seems reasonable to expect that if more potent preparations became generally available clinical advance would follow immediately. R. T. Frank,[3] having tested a number of commercial extracts, which, according to the manufacturers, had been biologically standardized, found that they had an activity varying from 0 to 30 per cent. of the amount claimed. Possibly, however, the values attached to many of the commercial products are calculated in terms of a smaller unit than that used by Shaw; and if this is the case it is to be hoped that soon there may be some international agreement on a unit of oestrual activity. The difficulties of standardization are well illustrated in a series of papers by Coward and Burn,[4] and Marrian and Parkes,[5] and Allan, Dickens, and Dodds.[6] Of these workers, Coward and Burn were the first to insist on the fact that the animals used for standardization gave a very varied response. They found that to produce oestrous changes in some rats needed the injection of eight times as much oestrus-producing hormone in oily solution as in others; and Marrian and Parkes, and Allan, Dickens, and Dodds, working with watery solutions, found a smaller but still significant range of variation in mice. Clearly, then, biological assay may lead to gross error, and it would appear that much of the early clinical literature is undependable, simply because the writers themselves were misinformed about the biological activity of the preparations used.

The recent isolation by Doisy[7] of crystalline oestrin has in all probability solved the problem of standardization; but until the process becomes established on a commercial basis and a crystalline oestrin is sold at a reasonable cost, clinicians will have to depend on relatively impure preparations standardized by the unreliable methods of biological assay. In connexion with Doisy's work the *Journal of the American Medical Association*[8] reports a sequence of events which cannot, in view of the commercial possibilities of crystallized oestrin, be without significance. It appears that Dr. A. Butenandt, assistant to Professor Windaus of Göttingen, learning that Doisy had reported his discovery before the International Congress of Physiology held in Boston in August, 1929, announced that he, too, had isolated the hormone of the female sex gland in chemically pure crystalline form. When, however, he published the description of his product in December he completely ignored the Doisy announcement. The writer of the article in the *Journal of the American Medical Association* caustically adds: "As might have been anticipated, the German investigator promptly conferred on his product a trade name controlled through a German manufacturer."

Meanwhile, fruitful work on the extra-ovarian hormones regulating ovarian periodicity has been proceeding, chiefly in this country, in Germany, and in America. Evans[9] in 1924 had observed that the injection of an extract of the anterior portion of the pituitary gland into the normal rat resulted in the temporary disappearance of the oestrous cycle. Later, Smith and Engle,[10] and Zondek and Aschheim,[11] showed that transplants of the anterior lobe produced premature puberty in mice, but had no effect on spayed animals. In 1928 Evans and Simpson[12] demonstrated that the two hormones of the pituitary—the oestrogenic hormone and the oestrus-inhibiting hormone—had different solubilities; alkaline extracts containing the latter hormone, which Evans had previously shown to have a growth-promoting effect and to produce luteinization of intact Graafian follicles, acid extracts containing the hormone which induces premature development of puberty. Zondek and Aschheim

showed that injection of urine from pregnant women into mice produced ovulation and precocious oestrus—effects which they concluded were due to the presence within the urine of anterior lobe hormones. On the basis of their findings they elaborated the now widely employed Zondek-Aschheim reaction for the diagnosis of pregnancy. Furthermore, they observed that implantation of fragments of human placenta was followed by hypertrophy of the anterior lobe, a phenomenon which also occurs normally in the pregnant animal. Working in Edinburgh, Wiesner[13] produced an active oestrogenic hormone by extracting placental tissue with sulphosalicylic acid, and, visiting Professor J. B. Collip's laboratory in September, 1929, he demonstrated, in what Collip has described as "a single but convincing experiment," the effectiveness of such an extract in producing premature maturity in the young rat. Collip, at Wiesner's request, looked for a method of concentrating this oestrogenic principle in placental extracts, and, according to a preliminary report published in the February issue of the *Canadian Medical Association Journal*, he has succeeded in obtaining this active principle as a micro-crystalline substance free from protein, salt, lipoid, and oestrin, which in an aqueous solution may be administered either subcutaneously or orally. Injection of amounts of the order of 0.01 mg. into the immature rat produced rapid development of the Graafian follicles, cornification and desquamation of the vaginal mucous membrane, and later appearance of corpora lutea. The hormone had very little effect on the normal adult animal. Pearl Claus[14] in 1929 reported the isolation of micro-crystals, producing a similar oestrogenic effect, from extracts of the anterior lobe pituitary body; but Collip, in opposition to all other workers, is inclined to the view that the hormone he has obtained from the placenta is produced by the placental tissue and not by the pituitary gland. Why at this stage of the investigations he should introduce such a complication of hypotheses is not clear; but whether events prove him to be right or wrong, Professor Collip is to be congratulated on adding yet another to his series of successful researches. Dare we express a hope that the absence from his paper of a detailed account of the method of extracting the placental hormone need not be assumed to foreshadow another patent?

Clinical work with the hormone of the corpus luteum and with the oestrus-inhibiting hormone of the pituitary body is even less advanced than work with the oestrus-producing hormone. The anterior pituitary hormone prepared by alkaline extraction is not yet available in any degree of purity, but the unexpectedly rapid development of the work on the female hormonal system encourages the hope that it will not resist isolation much longer. The pace at which discovery in this field is proceeding is sufficiently indicated by the fact that only five years after it had been shown that oestrus phenomena could be produced in castrated rats by injecting ovarian extracts, Doisy succeeded in isolating what appeared to be pure crystals of the oestrus-producing principle from material in which its greatest concentration was only one part in two millions. The whole series of researches, indeed, may serve as an indication not only of the skill of the modern biochemist, but of the rapidity with which biochemical discovery develops when it is concerned with material that can be investigated over a large field by animal experiment.

PREDESTINATION IN DISEASE.

MAN is born to trouble as the sparks fly upward; and among his inborn troubles are to be numbered several diseases. It is true that the word "diathesis," like the word "temperament," is not so frequently on medical lips as it was in the youth of some of us; but the whirligig of time, and the advance of science, are bringing these words, with an altered meaning, from beneath the clouds wherewith the rise of bacteriology overwhelmed them. The effect of words, even meaningless words, is very great. When the belief in "scrofula" and "struma" became untenable, "diathesis" was temporarily eclipsed. The expressions "inborn errors of metabolism," "idiosyncrasy," and "endocrine balance" have brought it once more into the light of day. And the word "diathesis" is not without its value. Even as with mass-produced motor cars one machine will show infinite superiority to its fellows, many of which possess a constitutional predisposition to trouble, so with the human machine some small inco-ordination in the working parts may produce liability to certain diseases. In his thoughtful lecture entitled "Predestination in disease," published in this issue of the *Journal* (p. 525), Dr. W. Langdon Brown discusses the effect that modern work has had on the doctrine of diathesis. Starting with Jonathan Hutchinson's definition of diathesis as "any condition of prolonged peculiarity of health giving proclivity to definite forms of disease," the lecturer proceeds to show how the failure to distinguish between liability to tuberculosis and infection by the tubercle bacillus helped to overthrow the doctrine. The overthrow was completed by such errors as the belief in a malarial diathesis, and the attribution of leprosy to eating unwholesome fish. Yet it was the same failure to comprehend the relation of soil and seed which helped to depose the bacteriological factor from its supremacy. The tubercle bacillus is ever present; all of us are exposed to its inroads; yet in most of us the seed falls upon stony ground. When these facts were realized a new interest was awakened in the subject of natural immunity.

While in the nineties Dr. Langdon Brown, as a student, was watching the death agonies of the older diatheses, Weismann was laying down the Calvinistic doctrine of the germ plasm. Later on, the discovery of the chromosomes and the rediscovery of Mendel's work seemed to place this doctrine on an assured basis; and the idea of predestination in disease was born. As Dr. Langdon Brown says, "the progress of human thought is always in a spiral; the turn of the spiral had now been reached; and back came diatheses, with a difference." The difference was between a concept intuitively arrived at and facts established by careful measurement. Kretschmer of Tübingen correlated physique studied anthropometrically with a number of well-defined psychological "temperaments." Draper, at Columbia University, is trying to establish by direct measurement the existence of certain facial types, such as the gall-bladder type, the peptic ulcer type, and the pernicious anaemia type; thus, in its ascent from turn to turn of the spiral, diathesis has passed from natural philosophy to science.

Modern researches are tracing further and further back the origin of factors which determine liability to disease. Dr. Langdon Brown mentions first those which express themselves through some recognizable chemical disturbance, such as albinism, alkaptonuria, cystinuria, pentosuria, and porphyrinuria. In four of these abnormalities metabolism stops short at a normal

intermediate product, owing to the failure or absence of an enzyme; and the product is then excreted in the urine. In albinism the individual is unable to manufacture any pigment containing melanin, although he can manufacture the pigments of blood and bile like an ordinary person. These inborn errors of function are, as the lecturer points out, the chemical analogues of structural malformation; they do not tend to get worse, but they may predispose to further trouble. They fulfil, in fact, Jonathan Hutchinson's definition of a diathesis. And in haemophilia we have a deadly disease, due to the lack of a particular ferment, which is transmitted according to definite Mendelian laws.

It is unnecessary to trace here the further course of Dr. Langdon Brown's argument, which he illustrates by idiosyncrasy, the sympathetic endocrine balance, and achlorhydria, to which 5 per cent. of the population is liable. Except inferentially, he refrains from speculating on what the future has in store for the victims of the neo-Calvinism of science. Already the researches of Hurst on achlorhydria lend hope to the suggestion that congenital achlorhydriacs may be able to take preventive measures by the daily absorption of HCl. The use of endocrine extracts may come to be placed on a sounder basis; defective enzymes may be supplied to assist metabolism; and the achievements of the thyroid and insulin may be rivalled in other directions. Just as the slightly defective mass-produced car may be coaxed or tuned into giving some sort of satisfaction, so perhaps the alkaptonuric may some day be induced to pass normal urine, and the albino to produce pigment. On the whole, the modern Calvin seems likely to be able to hold out more hope than his theological forerunner; and all-conquering man may yet produce something in the nature of antidotes to bodily predestination.

MENTAL CERTIFICATION IN SCOTLAND.

As the law stands to-day, the recoverable mental patient is in a much happier position in Scotland than in England. This is partly because there is widespread recourse to the voluntary mode of admission to the Scottish mental hospitals, and partly because in Scotland a patient can be placed in a private house or home for treatment for a period of six months, on the written recommendation of one doctor, without any legal intervention whatever. Patients may enter mental hospitals voluntarily in the early phase of their illness, and even if later their symptoms become acute they are not necessarily certified. Before the Act of 1913 it was necessary that patients who sought admission voluntarily should not be certifiable, but since the annulment of that provision a great impetus has been given to the adoption of voluntary treatment throughout Scotland. The privilege of admitting mental patients into private houses or homes without certification or legal formality exists in virtue of the well-known Schedule G of the Scottish Act of 1857, whereby it is permissible on the written recommendation of a doctor to place a patient for treatment in a private house or home for a period not exceeding six months, without certification or application to a magistrate or sheriff. The most curious feature of this schedule is, as Professor George M. Robertson, physician-superintendent of the Royal Edinburgh Hospital for Mental and Nervous Diseases, points out in his annual report, that it should have applied to private houses and homes, and not to mental hospitals. Probably the explanation is, as he surmises, that in 1857 there were but few private houses and homes, and these were not suspect, whereas in those days ill-treatment was known to occur in some of the asylums. Professor Robertson now makes the very interesting suggestion that, by a simple readjustment of the existing law, Schedule G should be made applicable to mental hospitals as well as to private houses and homes; in effect, he proposes for Scotland the abolition of certification in recoverable cases of mental illness. As an additional safeguard he would prefer that there should be recommendations from two physicians instead of one. In the course of his report he shows that this privilege of obtaining treatment in nursing homes has been available to the rich in Scotland for over seventy years, and contends that this privilege should now, in simple justice, be extended by law to the poor and to those of moderate means. "The application of Schedule G," he states, "would place the treatment of all classes on a footing of equality, and at the same time would remove the worst feature of our lunacy laws—namely, the certification of patients who are expected to make early recovery."

SOCIAL HYGIENE PROPAGANDA.

THE fourteenth annual report of the British Social Hygiene Council, for the year 1928–29, gives an account of many of the active steps which are being taken in this country and by international action to combat venereal disease. The view is expressed that a survey of the general statistics obtained from treatment centres justifies the inference that venereal disease is decreasing, and this is supported by the following facts: (1) the sequels of untreated disease are less frequent, particularly in the case of the certified deaths from syphilis of infants under 1 year old; (2) the incidence of venereal disease in the Navy, Army, and Air Force, an index of that in the civil population, has fallen; and (3) the number of persons suffering from recent infections with syphilis is fewer. Still more important in many ways is the change in public opinion which has taken place during the last twelve years. Before the agitation for the appointment of a Royal Commission no newspaper would mention venereal disease; at the present day the press is perfectly willing to give this aspect of social hygiene as much publicity as it allows to any other serious subject. The numbers of patients seeking advice at treatment centres because of the fear of having contracted venereal disease has again risen during the year under review; this might suggest the danger of propaganda producing a "phobia," but the council retorts that, nevertheless, "the best advice we can give is to urge those who have run the risk of infection to go at the earliest possible moment to the nearest treatment centre, without waiting for symptoms to appear." The work of the council in the past is abundantly justified by such results as are here indicated, but its immediate problem relates to the future. Under the new Local Government Act the grants hitherto made to the council by the Ministry of Health, and to the Scottish committee by the Department of Health for Scotland, will cease; they will be replaced by annual contributions from such local authorities as may be willing to make them. Attempts to secure amendment of the Act during the passage through Parliament were unsuccessful, but, as a result of urgent appeals, the Minister of Health has undertaken to issue a strongly worded circular to local authorities, pointing out the necessity for propaganda being financed by a central fund to which they should contribute. For the continuance of central services after March, 1930, the council will be dependent on the returning to it by each local authority of a quota of the central grant at the rate of five shillings per 1,000 of population. Every effort is now being made to bring the facts in regard to national propaganda before county and county borough authorities. The Society of Medical Officers of Health and its branches have rendered valuable assistance by recommending local authorities to support the national

propaganda of the council, and the British Medical Association has issued a letter on these lines to its members serving on public bodies. At the annual general meeting of the British Social Hygiene Council, Lord Linlithgow said that to him the position appeared hopeful, but it is obvious that if the valuable work of this body is to be continued all local authorities must be convinced of the necessity of propaganda. The present report in all its details contains ample material to secure such a conviction and to ensure the necessary action being taken.

SALE OF POISONS.

THE Departmental Committee which was appointed in July, 1926, to consider whether any modifications were necessary or desirable in the Poisons and Pharmacy Acts has just issued its report.[1] This embodies a short critical survey of present poisons and pharmacy legislation, and recommendations which in its view will simplify the law, strengthen the representative character and the disciplinary powers of the Pharmaceutical Society of Great Britain, attain elasticity and efficiency in the control of an authoritative list of poisons, and secure to the public reasonable facilities for obtaining poisons for agricultural, horticultural, industrial, and sanitary purposes, while keeping those who supply them under adequate control. The committee proposes that a new Pharmacy and Poisons Act should be passed into law, and that the profession of pharmacy and the control of poisons respectively should be kept distinct and dealt with in separate parts of the Act. It favours the continuance of the Privy Council as the central authority for pharmacy, recommending that it should have the power to nominate and determine the period of office of three additional members of the council of the Pharmaceutical Society. The committee further proposes that every person registered as a pharmaceutical chemist or chemist and druggist should become a member of the Pharmaceutical Society, any person ceasing to be so registered losing his membership. An increase in the disciplinary powers over chemists and druggists is involved in the recommendation that a "statutory committee" be appointed with power to remove from the register the name of any person who has been convicted of an offence against the Pharmacy Acts or of a criminal offence, or who has been guilty of any conduct which in the opinion of the statutory committee renders him unfit to be on the register. The statutory committee would have power to restore to the register any name or entry erased therefrom and the person concerned would have a right of appeal. Further recommendations of the committee (one of whose members, Mr. F. W. Gamble, signs a minority report) are as follows: That it shall be unlawful for any person not a registered pharmacist to use any description that might suggest that he or anyone employed in his business possesses any qualification with respect to the selling, dispensing, or compounding of drugs and poisons other than the qualification he in fact possesses; or to use the title of chemist in connexion with the retail sale of goods. It shall be the duty of the Pharmaceutical Society to enforce the provisions of Part I of the new Pharmacy and Poisons Act and to secure compliance by registered pharmacists with Part II, dealing with poisons, and the miscellaneous rules made in Part III; and to appoint inspectors, who shall be pharmacists and have powers to make their inspection effective, subject to the approval of the Privy Council as to the persons so appointed and their number. As from the appointed day, the Arsenic Act, 1851, and the provisions of the Pharmacy and Poisons and Pharmacy Acts relating to the sale, supply, and distribution of poisons, shall cease to have effect and for them the provisions of the new act shall be substituted. The committee recommends that the central authority for poisons should be the Home Secretary, assisted by a "poisons board," whose functions shall be to submit a poisons list to the Secretary of State, to consider or recommend any variation of the poisons list, and to assist the Secretary of State in making rules with respect to the sale or supply of poisons, and other matters relating to them. The poisons list, it suggests, should be divided into two parts: Part I to include poisons which may not be sold retail except by "authorized sellers of poisons"; Part II to include poisons which may be sold retail only by persons so authorized. Wherever possible, generalization should be avoided in the poisons list, and the poisons therein should be individually defined. With regard to poisons in Part I of the poisons list it is suggested that power be given to prohibit the retail sale of such of these poisons as may be specified except on the prescription of a registered medical practitioner, dentist, or veterinary surgeon, and that power be given to provide by rule for prescribing the form and regulating the use of prescriptions. The purchaser of poisons in Part I must either be certified in writing, or be known by the seller or by an authorized deputy, to be a person to whom the poison may be properly sold; and the seller must enter in a book kept for the purpose the name and address of the person giving the certificate. Persons other than "authorized sellers of poisons" may on application in writing, and on payment of a fee, have their names placed on a list of persons entitled to sell, on authorized premises, poisons in Part II. The use by any such person of a description calculated to suggest that he is entitled to sell any poison other than one in Part II shall be punishable by a fine not exceeding £5; and anyone so registered shall have his name removed from the list and for a specified period be disqualified from having his name on it if he is convicted of an offence against the Pharmacy Acts or any criminal offence rendering him unfit to have his name on the list. We hope in a later issue to return to the report of the Departmental Committee and to consider its recommendations in detail.

TULARAEMIA.

A FEW weeks ago[1] we drew attention to the prevalence of tularaemia as an endemic and sometimes an epidemic disease in Russia, and commented on its public health significance. At the time of writing the disease had been reported from that country only, but it had had a wide distribution and a long history, and it is no surprise, therefore, to find that tularaemia has recently been recognized much further west. In January of this year Dr. Th. Thjötta described three cases from Norway, and in a letter to us he mentions that at least eight other cases have been subsequently diagnosed. All the patients had a history describing a close association with hares. The three published cases occurred in hunters who had shot and cleaned hares shortly before developing the disease; the others included game dealers and kitchen maids who had skinned or otherwise prepared these animals for the table. There is little doubt that, as in Russia, the disease is not a new one in Norway. The present cases have all been associated with hares, but other rodents may be implicated, and it is suggested that a disease in man called "lemming fever," and attributed by the laity to contamination of water with dead lemmings, may also be tularaemia. There is, however, no definite proof yet that this is so. So far, apart from a few laboratory infections, tularaemia has not been recorded in Britain; but neither was it diagnosed on the Continent until recently, although there is a mass of evidence to support its antiquity. It is essentially a disease of rodents, and when the condition occurs in man it is

[1] *British Medical Journal*, February 22nd, p. 345.

always associated with contact with these animals. The commonest reservoirs of the infection are the game and fur rodents, and so far as Britain is concerned the former class must be the more important. The microbe is transmitted by inoculation, either through the agency of an insect or arachnid vector or through actual contact with the infected animal. As a rule, the disease runs a benign course, but the clinical symptoms vary considerably. Generally, however, there is a painful enlargement of the lymph nodules in the region of the inoculation about twenty-four hours after infection. An ulcer develops in about 80 per cent. of the cases, commencing as a painful red papule which heals slowly and is accompanied by a general fever and malaise. Sometimes the primary lesion is absent, and sometimes there are no symptoms other than fever and general weakness. Although the mortality is low—it is estimated as about 3 per cent.—convalescence is slow, but a permanent immunity results.

FIRST AID IN COAL MINES.

REGULATIONS regarding first-aid and ambulance services at coal mines, which come into force on April 1st, have been issued by the Board of Trade. All mine-owners are required to arrange for first-aid treatment in cases of accident and sickness occurring in or about their mines. The regulations refer to surface, underground, and transport organization. Where more than a hundred persons are employed in any one shift a first-aid room, in charge of a qualified nurse or doctor or certificated supervisor, must be adequately equipped and maintained at the surface. These provisions apply to smaller mines, but, in the absence of a room, a shelter affording protection from exposure is sufficient. With certain exceptions a prescribed number of underground workers, normally thirty, must be qualified first-aid men, who will be distributed as far as *practicable among groups of miners* working regularly at the same part of the pit. Every underground worker must be supplied with a portable first-aid outfit unless first-aid men are provided with boxes. In any case all such equipment must be examined at the surface at the end of a shift, and replenished if necessary. First-aid stations must also be organized and provided with stretchers, splints, and dressings. Owners are further directed to arrange for an effective motor ambulance service to be stationed at a base not more than ten miles by road from their mines, and it must be accessible by telephone if their underground workers exceed ten in number. Where necessary, shafts and pits must be fitted with appliances for raising the injured with the least discomfort.

OLD MEDICAL BOOKS.

ON March 20th a fairly extensive collection of old medical books was sold by auction at Messrs. Hodgson's Rooms in Chancery Lane. The only incunabulum (a book printed during the fifteenth century) in the catalogue was a Salernian "Regimen Sanitatis" by Villa-Nova, Venice, 1500; but quite a number of scarce books of the sixteenth century were offered. For example, Boorde's "Breviary of Healthe . . . expressing the obscure termes . . . concernyng Physicke and Chierurgerie," black letter, 1552; a German edition of Paracelsus on Surgery, published at "Franckfort," 1555 (and another German edition of Paracelsus, Strasbourg, 1603); Bretschneider on Health, 1564; a work of the Salernian school on the same subject, 1568; Nicolo Viti on Tumours, Rome, 1585; Roesslin on Midwifery, edited by Raynalde, 1565; two Galens from Lyons (one of them on Fevers), 1547 and 1550 respectively. Then there was F. Barbarus (physician to Lorenzo de Medici) on Gynaecology—a manuscript on 119 leaves of vellum which has never been published, so far as is known—also from the sixteenth century. Among editions of the following century were to be noted a Hippocrates of 1657; Sennart's works, 1654-56; Carie's "Farewell to Physicke," sixth edition, 1611—only two other copies of this are known; the first edition of Harvey's "Anatomical Exercitations concerning the Generation of Living Creatures, to which are added Particular Discourses of Births, and of Conceptions," 1653; a Proclamation forbidding any citizen from seeking the royal touch for the cure of the King's Evil, published 1630, and due to the prevalence of plague and a fear that the King might thus be infected; Frommann on Haemorrhoids, 1677; Diemerbroeck on Anatomy, 1683; Devaux's "Le medecin de Soi-Meme," 1682. Then followed a long list of eighteenth century productions, including one on the Uses and Abuses of Coffee, 1760. Later in the day there was a treatise by Cardan, published at Venice in 1536, apparently as a defence of old-fashioned as against new-fangled methods of treatment; a very rare book in Spanish on (American) Indian drugs and remedies against poisons, by Monardes, published at Seville, 1565; a short practice of surgery by Schylandrus, Antwerp, 1577; and an Aldine history of medical worthies, Venice, 1547. On the same day, March 20th, Messrs. Sotheby of Bond Street were selling a very early treatise on veterinary medicine—namely, that of John Ruellius, Paris, 1530, bound in morocco with the arms of Pope Paul III on the cover.

OXFORD OPHTHALMOLCGICAL CONGRESS.

THE twentieth annual meeting of the Oxford Ophthalmological Congress (founded by the late Robert W. Doyne) will be held under the presidency of Mr. A. Bernard Cridland on July 10th, 11th, and 12th, 1930. The members will assemble at Keble College on the evening of Wednesday, July 9th, and on the following morning there will be a symposium on toxic amblyopia, to be introduced *from the ophthalmological standpoint* by Dr. H. M. Traquair of Edinburgh, from the point of view of the physician by Sir Farquhar Buzzard, Bt., and from the pharmacological aspect by Professor J. A. Gunn. In the afternoon an address will be given by Sir Oliver Lodge, F.R.S., entitled "Modern theories on the nature of light." The Doyne Memorial Lecture will be delivered on the morning of July 11th by Dr. Harry Friedenwald of Baltimore, the subject being "Pathological changes in the retinal blood vessels and their significance." Addresses will be given by Professor Artur Schüller of Vienna, on recent developments in radiology associated with ophthalmology, and by Professor Jules Gonin of Lausanne, *on detachment of the retina and its treatment*. A number of independent papers will be read and the Friedenwald ophthalmoscope will be demonstrated. There will also be demonstrations in the scientific and commercial museums. The annual dinner will take place in the Hall of Keble College on July 10th. The full programme of the congress is to be issued in June. All communications should be addressed to Mr. C. G. Russ Wood (12, St. John's Hill, Shrewsbury), who is again acting as honorary secretary.

ON the occasion of the fiftieth anniversary of the foundation of the Ophthalmological Society of the United Kingdom, the Bowman Lecture will be given by Sir Arthur Keith, M.D., F.R.S., on Thursday, April 3rd. His subject is "The genius of William Bowman."

AT a meeting of the medical and science councils of the People's League of Health, on February 4th, a committee was appointed to survey the situation regarding tuberculosis of bovine origin in Great Britain; representatives to serve on the committee have been appointed by the Royal Colleges of Physicians and Surgeons.

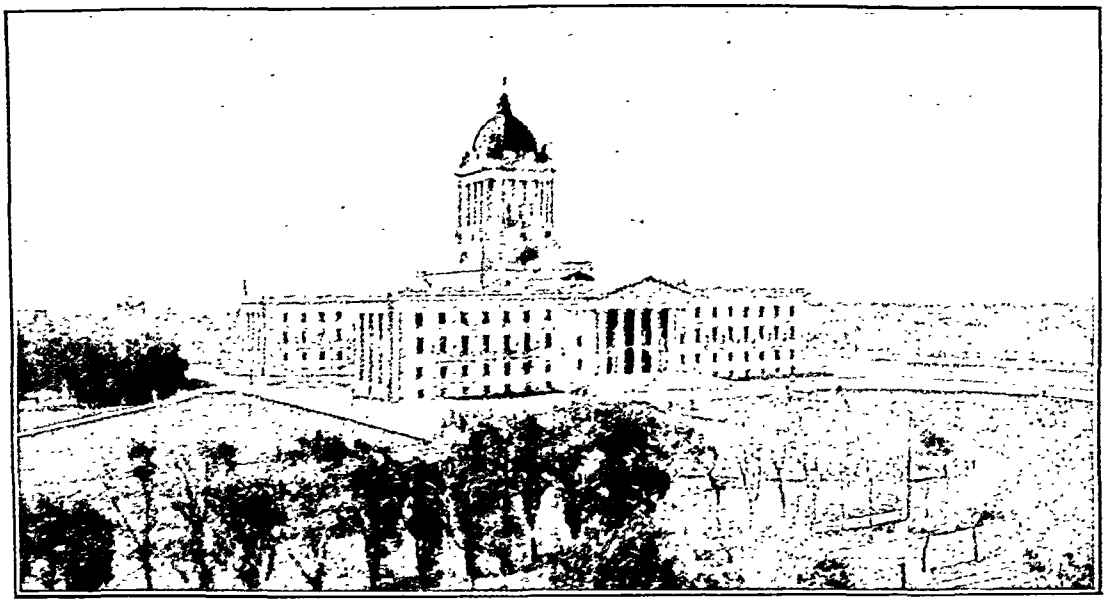
NINETY-EIGHTH ANNUAL MEETING
of the
British Medical Association,
WINNIPEG, 1930.

THE ninety-eighth Annual Meeting of the British Medical Association will be held at Winnipeg next summer in conjunction with the sixty-first Annual Meeting of the Canadian Medical Association, under the presidency of *Professor* W. Harvey Smith, who will deliver his inaugural address on Tuesday, August 26th. The scientific and clinical business of the meeting is being organized in fourteen Sections, which will hold their sessions on Wednesday, Thursday, and Friday, August 27th, 28th, and 29th, the mornings being given up to discussions and the reading of papers, and the afternoons to demonstrations and special addresses. The names of the officers of Sections, with other preliminary notes, were published in the *Supplement* of February 15th, and further details of the arrangements will appear from time to time in later issues. Members who propose to take part in the meeting should write at once for particulars about the journey by sea and land to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, London, W.C.1. The Winnipeg office is at 102, Medical Arts Building, Winnipeg, Manitoba. We publish below the third of a series of historical and descriptive articles on Winnipeg and its surroundings, contributed by Dr. Ross Mitchell; the first appeared on January 4th (p. 32), and the second on February 15th (p. 300).

MANITOBA.

IN 1867 four provinces, Ontario, Quebec, Nova Scotia, and New Brunswick, which up to this time had been politically separate, entered into confederation and the Dominion of Canada was born. One of the first problems to be dealt with by the first Federal Government was the creation of a new province out of that vast district west of Ontario which was under the control of the Hudson's Bay Company. Some preliminary work had already been done. In 1859 the licence of the Hudson's Bay Company was due to expire, and the Parliament of Canada of that time, which meant Ontario and Quebec, petitioned the British House of Commons not to renew the licence. A committee of the British Parliament was appointed to investigate the matter, and after hearing evidence reported that the districts along the Red and Assiniboine Rivers were likely to be needed soon for settlement: "Arrangements should be made by which these districts may be ceded to Canada upon equitable principles, and within the districts thus annexed to her the authority of the Hudson's Bay Company would, of course, entirely cease." Meanwhile the Canadian Government sent out an exploring expedition under S. J. Dawson and Professor Hind. Dawson's duty was to survey a road from Lake Superior to Fort Garry at the junction of the Red and Assiniboine Rivers, while Professor Hind was to report on the vegetation and soil of the country. Parts of the Dawson road are still being used and Hind's report was illuminating. It is of interest to note that R. M. Ballantyne, the novelist, was one of Hind's party.

As a result of the investigation, the new Federal Government decided to purchase the rights of the Hudson's Bay Company. For a payment of £300,000 the Company surrendered its rights in Rupert's Land, reserving only one-twentieth of the fertile land and a reserve of 500 acres around each post. Thus, in Winnipeg a large area on which are located the old gateway of Fort Garry, the Fort Garry Hotel, the new Hudson's Bay store, and the Legislative Building is still known as the Hudson's Bay Reserve.

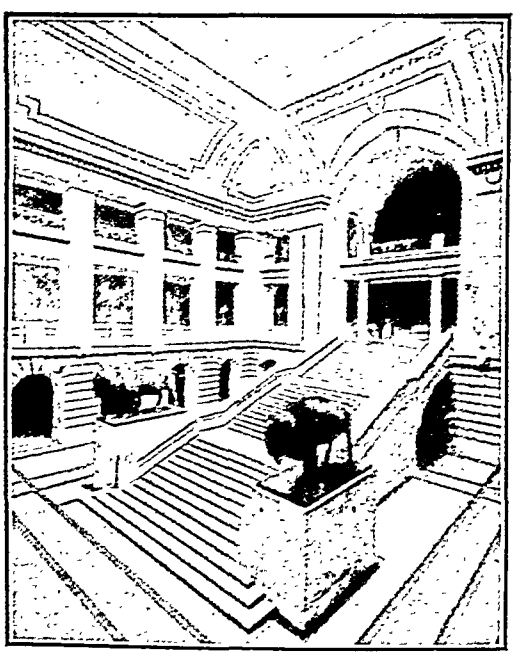


Birth of a Province.

The new province, Manitoba, entered Confederation on July 1st, 1870. Its birth, however, was not uncomplicated. A large number of the inhabitants of the Red River Settlement were French half-breeds or Métis, and the prospect of an influx of settlers from Ontario, English-speaking and of another religion, who would till the soil and drive away the herds of buffalo on which the Métis had depended for subsistence, did not please them. The arrival of Canadian surveyors to institute a new square block survey of land in place of the long narrow river lots served to fan the discontent. Under the leadership of Louis Riel, a young man who had received education for the priesthood, but had never taken orders, the discontent broke out into flame. A Provisional Government was formed, Fort Garry was seized, the Hon. Wm. MacDougall, who had come from Ottawa to be the new Governor, was not suffered to enter, many prominent citizens were imprisoned, and, finally, a young Irish-Canadian, Thomas Scott, was shot after a mockery of a trial. The fate of Scott created intense indignation in Ontario. It was agreed with the British Government that an armed force supported by both Governments should be sent out. This force was composed of British regulars and volunteers from Eastern Canada under Colonel (later Field-Marshal Lord) Wolseley, and after struggling through the wild rocky region between Lake Superior and the Lake of the Woods, reached Fort Garry in August, 1870. Just before the arrival of the advance guard Riel and his two lieutenants, who by that time had been deserted by most of their followers, quietly slipped out of the fort and the Provisional Government ceased to be. It is of interest that among Riel's prisoners in Fort Garry were Dr. J. C. Schultz, afterwards Sir John Schultz, fifth Lieutenant-Governor of Manitoba, and Dr. Cowan.

The name Manitoba is derived from two Indian words, Manito-bau, the "Spirit Strait." In the narrows of Lake Winnipeg there is an island on which the limestone is very compact and resonant. When the waves beat against the beach the roaring sound was thought by the Ojibways and Crees to be due to a Great Spirit beating a drum. The early spelling was Manitobah, the accent being placed on the last syllable, but the final "h" was soon discarded and the accent is now on the third syllable.

Growth and Development.



As first constituted Manitoba was square in outline and so small that it was called "the postage stamp province." In 1881 the boundaries were extended, and in 1912 a further extension of the boundary northward gave Manitoba the two best harbours on Hudson Bay—Nelson and Churchill—and 500 miles of coast-line. By this change the tiny province of 1870, containing 13,000 square miles, reached its present size of 251,000 square miles, just double that of the British Isles. The Hudson's Bay Railway, long thought to be only a visionary enterprise, has, by the action of the Dominion Government, become a fact, and steel has been laid from Le Pas, Manitoba, on the Saskatchewan, to Churchill on Hudson Bay. Close to its terminus lie the ruins of Fort Prince of Wales. The first fort was built by

LEGISLATIVE BUILDING, WINNIPEG, MANITOBA.

the Hudson's Bay Company in 1633; after its destruction by fire another, of tremendous strength, was built by Marlborough's engineers. In 1782, the French, under Admiral La Perouse, surprised the fort, captured it without firing a shot, and blew it up. In 1930 passenger trains will be running from Churchill to Winnipeg on a well-ballasted track.

Mention of the railway summons up visions of how transportation has been effected in the past. The first means of transport used by the fur traders was the birch bark canoe, which had the merits of lightness, buoyancy, ease of repair, cheapness, and ease of construction, as all the materials necessary could be found in the forests. They were, however, very vulnerable, and they could not be used to convey very heavy or bulky objects. About 1826 one of the Hudson's Bay Company's factors introduced the York boat, modelled after the old Norse galleys. The York boat was of a type light enough to be taken on rollers over portages, strong enough to shoot the rapids, sufficiently seaworthy to cross such stormy lakes as Lake Winnipeg, and with accommodation for carrying a cargo of eight pieces, each of one hundred pounds, besides a crew of eight voyageurs, including bowsman and steersman. They were propelled with oars about twenty feet long and with one large square sail.

GRAND STAIRWAY, MANITOBA LEGISLATIVE BUILDING.

As the Red River Settlement increased in numbers the settlers' needs could not be met by the Hudson's Bay ship which came annually to York Factory on Hudson Bay. Traffic sprang up between the Red River Settlement and St. Paul in Minnesota, which was on a line of railway. Goods were transported in brigades of Red River carts drawn by oxen or native ponies. These two-wheeled carts were made entirely of wood, and could be made with only a saw, chisel, and draw-knife. Each cart could carry about one thousand pounds. These, in turn, were superseded by flat-bottomed stern-wheel steamboats, which for some twenty-five years travelled up and down the Red and Assiniboine Rivers between points in Manitoba and Minnesota. In 1878 railway communication was established between Pembina in Minnesota and St. Boniface across the Red River from Winnipeg, and in July, 1881, the first train of the Canadian Pacific Railway entered Winnipeg. Within the last few months arrangements have been completed for regular air mail service throughout the West.

Manitoba's first Cabinet was formed on June 12th, 1871, when the total provincial population was 11,693, of which the white race numbered 1,565. When Winnipeg was incorporated, in 1873, the new city could muster only 215 inhabitants. The present population of Greater Winnipeg is 336,202, and the population of Manitoba in 1926, according to the Dominion census, was 638,000, of which only a few thousand were Indians. When Manitoba entered Confederation the Dominion Government retained control of the natural resources. Repeated attempts were made by provincial Governments to have these resources transferred to the province, but it is only within the last months that these efforts have been successful. How valuable these natural resources—water power, forests, and, above all, minerals—are, no one can say, but the present indications are that as further development takes place they will prove to be tremendous assets. The Minister of Natural Resources has recently stated that the water power available in the Nelson, Churchill, and Winnipeg Rivers in the province totals 5,000,000 horse power.

The New Legislative Building.

Much of the history of the Red River Settlement and Manitoba has been incorporated in the new Legislative Building. The design of the architect of the building, Frank Worthington Simon, F.R.I.B.A., Liverpool, was that that which was best in the Past should be preserved and wrought by the hand of the Present into the structure emblematic of Manitoba—"The Land of the Great Spirit." The southern entrance looks toward the Assiniboine River, along which passed the early explorers, fur traders, and colonists. At the eastern entrance are the stone figures, in heroic size, of La Verendrye, the first white man to open up the Canadian West, and Lord Selkirk, the first to establish a colony. At the western entrance one sees the figure of Wolfe, who, visioning Canada as one of the units of the British Empire, gave his life for that vision, and of Lord Dufferin, the first Governor-General of Canada to visit our West and catch a glimpse of its possibilities. In 1877 he spoke these words in Winnipeg: "Manitoba is destined to be the keystone of a mighty arch of sister provinces stretching from the Atlantic to the Pacific." Most impressive is the main entrance, which, prophetically, looks to the north. Six fluted columns of stone with Ionic capitals support an entablature in which Alfred Hodge has portrayed an allegory of the Dominion which is worthy of much study. The stone of which the building is constructed carries the mind back to far-off geological periods. It is a limestone, quarried at Tyndall near Winnipeg, of great strength and beauty, bearing marks of fossil ferns and aquatic animals.

Entering by the north one sees the main staircase flanked by two bronze buffaloes, emblems of the province, sculptured by Gardet of Paris. The staircase leads to a rotunda under the dome, and the eye is arrested by the great Brangwyn mural painting of scenes in the great war. The legislative chamber is one of quiet dignity and beauty. The mural decorations by Augustus Tack are woven about the theme "The Origin of Legislation." On either side of the Speaker's chair are massive bronze statues of Moses and Solon.

From the centre of the building rises a square tower surmounted by a dome on which is poised the gilded bronze figure of a boy typifying Eternal Youth, the Spirit of Enterprise. The figure was cast in a foundry seventy miles from Paris. During the war the foundry was completely destroyed by bombing, the figure alone remaining unscathed. It was rushed to a seaport and put in the hold of a vessel bound for America. Before it drew out of port the boat was commandeered to transport American troops, and for two years the bronze figure was carried in the ship through submarine infested waters. At the close of the war it was brought to New York and thence to Winnipeg. The attitude of the boy, who seems to have paused for a moment while in flight, is that of a runner, his face to the north, signifying that the spirit of enterprise, capable of enduring hardships, sees the vast possibilities of the Northland, with its wealth of natural resources. Under his left arm he carries a sheaf of golden grain, and in his right hand, uplifted, he holds a torch, *vitae lampada*, recalling McCrae's lines:

> "To you from failing hands we throw
> The torch; be yours to hold it high!"

Nova et Vetera.

A SCOT IN WALES, 1600–1620.

WE are indebted to the Cymmrodorion Society (64, Chancery Lane, London) for publishing an account of *A Scottish Surgeon in Wales in the Seventeenth Century*, and to its author, Marjorie Foljambe Hall, F.R.Hist.S., for sending us a copy of the study. The surgeon in question, Alexander Reid or Rhead, does not appear to have been a person of very great ability; Sir D'Arcy Power, in the *Dictionary of National Biography*, said that he made no additions of importance to the theory of medicine. The pamphlet is worth reading, however, for its picture of medical practice in the early seventeenth century, and because it contains some hitherto unpublished papers that throw fresh light on Reid's career.

Reid can hardly be said to have lived in Wales, but he settled at Holt and Chester near the border, and for nearly twenty years he apparently had an extensive consulting practice as a physician in North Wales, especially in Denbighshire. A great deal of this practice was conducted by letter, for at that time, as is well known, not only patients, but apothecaries and surgeons, consulted physicians in this way, and the latter gave many prescriptions on hearsay and without troubling to interview the patients. More than a century later we find Dr. Alban Thomas of Cardigan consulting Sir Hans Sloane by letter and getting a prescription from him (see "An eighteenth century practitioner," *British Medical Journal*, 1925, i, p 853).

Sir Roger Mostyn was a warm patron of Reid's and recommended him to his son-in-law, Sir John Wynn of Gwydir, for whom Reid prescribed an "operative julep." Unfortunately, Wynn sent this prescription to the Welsh physician, Sir Thomas Williams, asking his help in getting it made up. Williams no doubt resented this; at any rate, he criticized Reid's knowledge of Welsh simples and his prescription generally. Wynn's letter to Williams is not extant, but it appears that he incautiously communicated some of Williams's strictures to Reid, who wrote: "In your worship's last lettir a fownd enclosed a brefe schedul of your owin to Sir Thomas Williams, wherein you desyre his furtherance for the making of ye julep. His answer I redde wryten upon the back of it. But becaus in it I perceaued a selfe loone, a disdayne of others, & a censuring humor, here brefely I will examin every poynt of it." He then went on to combat his rival's arguments and support his own julep and extol its constituents. Herein was the making of a very pretty quarrel, for Williams not only condemned the prescription and asserted that many of the simples were not to be found in Wales, but he also questioned Reid's diagnosis, alleging that the disease was hepatical and not splenetical. The storm raged over the advisability of using rhubarb, which Reid condemned and Williams recommended. Whether there was any counterblast from the latter we do not know, but it is apparent that Reid kept the confidence of Sir John Wynn.

There is a curious reference to asparagus in Reid's long letter: "As for Asparagus, seeing it is a woord signifying many thinges, as one may reed in the epistel of the learned Fallopius to Mercurialis . . . it is a farre harder mater to fynd now the usual sperage than grasse rootis." Grass roots were prescribed apparently by Reid in his julep recipe, and Williams seems to have scoffed at them. It seems to have been a very typical medical dispute, in which each party quoted Terence against his colleague, and we are curious to know how it ended, if, indeed, it ever did. If the "schedul" of Wynn was brief Reid's reply was not, for it covered three closely written foolscap pages. Looking at the matter across the perspective of three centuries, it seems to have been a dispute between the advocates of active and expectant treatment, for rhubarb would doubtless have made its action felt, whereas no "grasse rootis" grown in this country could have been expected to do so.

Miss Foljambe Hall tells us of some of Reid's distinguished patients, such as the fourth Earl of Pembroke, to whom he dedicated his *Treatise of the first part of Chirurgeric* in 1638. We confess that we do not know in what circumstances an Earl of Montgomery and Pembroke was created Baron of Shurland in Sheppey, but we are glad to come across an authentic holder of the title of the doughty baron of that ilk and of the *Ingoldsby Legends*, who, after successfully defying the law, ecclesiastical and civil, came to a premature end only by witchcraft (and a septic great toe). Among other distinguished patients of Reid's were the Earl of Bridgewater, Lord President of Wales, and Lord Gerard, President of the Council of the Marches of Wales, and the Salusburys of Llewenny.

Reid's residence on the Welsh border ended about the year 1620. Sir D'Arcy Power has told, in the *Dictionary of National Biography*, the events of his subsequent career as graduate of Oxford and of Cambridge, and Fellow of the Royal College of Physicians of London. There is a short notice of him in Munk's *Roll of the Royal College of Physicians*.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT, 1928-29.

I.

In a preface to the *fifteenth annual report*[1] of the Medical Research Council, the Committee of the Privy Council for Medical Research states that a grant of £148,000 was provided by Parliament for the Medical Research Council during the financial year, and with this amount, supplemented by private benefactors and various public bodies interested in certain aspects of research work, the Council was able to undertake a total expenditure of £168,000. The Committee draws special attention to the fact that legacies or gifts to the Medical Research Council are applied to scientific work conducted through an already existing organization, and are thus used without reduction or delay. During the past year Professor E. P. Cathcart and Sir Charles Sherrington have retired from the Council under the terms of the Royal Charter, and in their places Professor J. J. R. Macleod and Mr. Wilfred Trotter became members of the Council from October last. Sir Charles P. Trevelyan also resigned upon becoming President of the Board of Education, and Mr. A. G. Church, M.P., has been appointed in his place. Viscount D'Abernon has been appointed chairman of the Council in succession to the Earl of Balfour, who resigned for reasons of health.

GENERAL SUMMARY.

Following a precedent set on two previous occasions the report opens with an introduction in which, together with the usual summary of the events of the past year, the experiences of the last five years are reviewed. The past year has seen the completion of the new extension of the National Institute at Hampstead, which a bequest of the late Lord Justice Ronan enabled the Council to construct. No capital grant has ever been made to the Council for the provision of the Institute; the main building, formerly a hospital, together with a nurses' home, was bought with its freehold site in 1914, for a sum that now seems trifling, out of the non-expended portion of the first year's income. During the war the building was lent to various authorities, and out of savings accumulated during this period it was possible to provide the minimum scientific equipment for the Institute and the freehold site of nearly forty acres for the Farm Laboratories at Mill Hill. In each succeeding year development has been achieved out of annual income, and two recent bequests have rendered possible the establishment of an Institute that is worthy of the distinguished scientific work done within it by the staff.

Among the important activities of the Council during the past five years has been the formulation of standards for biological measurement. The establishment, maintenance, and application of such standards involve the work of highly qualified investigators in its several phases, but when the Therapeutic Substances Act was enacted the Council, in view of the steady progress maintained at the Institute, was able to accept the responsibilities legally put upon it by the Regulations of 1927. The standards must now be issued to all manufacturers of the scheduled substances, who are legally bound to apply them, and this naturally means that the Institute has had to undertake an increasing amount of work, experimental and administrative. Furthermore, it has supplied the British standards both to the overseas Dominions and to the official organizations of several foreign countries.

The Council believes that no part of the work it has directly promoted has greater biological interest or practical importance than that concerned with virus diseases. These studies "are concerned with an invisible underworld of bodies that . . . cannot be seen as definite structures by ordinary microscopic means, and the relation to them of certain objects made visible by special optical methods is still a matter of discussion." The policy of the Council has been to leave various skilled members of its staff completely free to select particular virus diseases for study, and work may be said to be upon two converging lines of effort. Along the one line attempts are being made to imitate the natural immunity which usually follows an attack of a virus disease; and along the second, investigations are conducted upon the properties and natural history of the virus itself. The Council notes the success that has been obtained in making dogs resistant to distemper, and fowls to fowl-plague. These two examples of protection have led to the successful use of similar methods in the protection of monkeys against yellow fever, but it is still doubtful whether a treated vaccine derived from "monkey virus" will protect man. So far, however, attempts to place other virus diseases—for example, foot-and-mouth disease, measles, and, according to some, influenza and common colds—under similar control have not yielded good results. The difficulties are various: foot-and-mouth disease itself gives no lasting immunity to a second attack; the only animal affected by the virus of measles is the monkey, but the disease cannot be passed from monkey to monkey; influenza is not transmissible at all to animals. "We can only hope," says the Council, "that means will be found to surmount difficulties of these kinds." Meanwhile the work on the actual nature of virus particles proceeds in many centres. Of special importance are Mr. J. E. Barnard's studies on the better optical examination of virus by using shorter wave-lengths beyond the visible spectrum; Dr. W. E. Gye's work upon virus and cancer; observations by Dr. C. Todd upon the cellular "individuality" of the animal body; and the studies in comparative pathology made possible by developments at the Farm Laboratories at Mill Hill.

The remainder of its introduction the Council devotes to a brief account of recent advances in radium therapy, and in the study of the physiology of the special senses; to a statement about the publication in progress of a *System of Bacteriology* in nine volumes, three of which have appeared; and to an important survey (discussed in the *Journal* of March 15th at page 503) of the problems of clinical research and experimental medicine.

WORK AT HAMPSTEAD AND MILL HILL.

Following the usual custom, the report proceeds to describe under their appropriate headings the investigations carried out at various centres. Biochemical and pharmacological researches conducted at the National Institute under the direction of Dr. H. H. Dale are steadily building up evidence to show that there are many delicate mechanisms for regulating this or that function of the body which depend on the production, under a given stimulus and in a localized area, of an active chemical substance of the histamine type. Yet another intensely active substance, extracted from the spleen of large animals, has been identified as acetylcholine. The demonstration that this substance, hitherto known only as an artificial product of synthesis and as a rare constituent of certain plants, occurs naturally in the animal body throws light on many physiological phenomena. Extremely minute doses injected into the circulation reproduce the effects of stimulus to the autonomic nervous system, and evidence from different sources points to the probability that the effect produced by certain kinds of nervous stimulus in the body—for example, the local flushing and heat which accompany localized pain—are due to the liberation of this or some closely allied substance near the end-points of the nerves. This, taken with the evidence of the extensive distribution of histamine in the body, offers a basis for a wider conception of a chemical machinery concerned in making delicate adjustments of the circulation to local physiological needs.

Dr. H. King and Dr. G. A. C. Gough have continued their search for synthetic substances having specific curative actions in particular protozoal diseases, while Dr. King is also studying the somewhat mysterious constitution of muscarine. Dr. O. Rosenheim is continuing his work on the chemistry of vitamin D and its relation to ergosterol,

[1] Report of the Medical Research Council for the year 1928-1929. H.M. Stationery Office. 1930. Cmd. 3426. 3s. net.

and has completed his work on a specific colour reaction for ergosterol. The work in experimental pathology has largely been concerned with virus diseases, as already indicated. The special activities of the past year have included studies of vaccinia in rabbits by Captain S. R. Douglas, with Dr. Wilson Smith, and by Dr. C. H. Andrewes on the mode of action of immune serum in infections by various viruses.

Dr. W. E. Gye and Dr. W. J. Purdy have continued their studies at Mill Hill upon filtrates of the Rous sarcoma, but for the moment have abandoned this part of the investigation, and have turned their attention to the study of immunity reactions in cancer. These are of two kinds—namely, immunity to grafts of living tumour cells, and immunity to the virus of filterable tumours. Many years ago it was proved that animals could be made resistant to cell grafts by the inoculation of living cells, especially embryonic cells of the same species. A tumour of the mouse, which was used in the experiments whereby this fact was proved, has been found in the course of the present investigations to have developed a relative insensitiveness to this form of tissue immunity. Experiments with lead selenide as a curative drug in cancer have yielded negative results.

Work on encephalomyelitis, which is occasionally associated with dog distemper, has been the main subject of inquiry by Dr. J. R. Perdrau, while Mr. G. W. Dunkin has continued his study of Johne's disease in cattle. The diagnostic agent "johnin" prepared by him is being used in many parts of the world, with, on the whole, satisfactory results, but some advanced clinical cases have failed to give positive reactions. Mr. C. Dobell has continued his work on the intestinal protozoa of monkeys and men, and towards the end of 1928 he succeeded for the first time in isolating *Entamoeba coli* in pure culture from *M. rhesus* and *M. sinicus*. The isolation of a pure simian strain of *E. coli* enabled Miss Bishop to make a detailed study of the action of emetine on this species *in vitro*. The results of this work show that emetine is about fifteen times less toxic *in vitro* for *E. coli* than it is for *E. histolytica*.

The Department of Applied Optics, now returned to the main building at Hampstead, has concentrated its work upon the problems directly or indirectly associated with the study of filter-passing viruses, particularly on the microscopic side. The practical difficulties of using ultra-violet light are being slowly overcome, and dark-ground photography with this form of radiation is being specially studied. Professor Leonard Hill and Dr. Argyll Campbell in the Department of Applied Physiology and Hygiene, in attempting to throw light on physiological problems of deep-sea diving, have studied the effects in animals of prolonged exposure to high tensions of oxygen. It has been shown that the poisonous high tension of carbon dioxide in the tissues can best be removed by lowering the proportion of oxygen in the mixture breathed. On the other hand, the process of decompression of divers can be greatly accelerated if pure oxygen is breathed for a short time. Mr. H. J. Taylor of the London Light Clinic and Mr. T. C. Angus have been investigating the infra-red region of the spectrum, and Professor Leonard Hill and Dr. Eidinow have continued their studies on the biological effects of ultra-violet radiation. Dr. R. B. Bourdillon and Mr. T. A. Webster, with several other workers, have extended their investigations on the products of irradiation of ergosterol, and a spectroscopic change, *hitherto undescribed*, has been identified as occurring in the initial stages of the irradiation.

BIOLOGICAL STANDARDS.

Various serological standards are issued in a regular manner under the Therapeutic Substances Act, and examination of samples of the different makes of therapeutic serums offered for use in this country has been continued. Mr. P. Bruce White has investigated the various methods of standardization that have been proposed for assay of anti-gas gangrene (*B. welchii*) serum. An examination into the scientific basis of the toxicity tests used for novarsenobenzene has been completed, and a full report has been published (*British Medical Journal*, March 23rd, 1929, p. 568). The British standard of digitalis has been carefully studied with outside help from Dr. J. H. Burn, Dr. J. W. Trevan, and Professor Bijlsma of Utrecht, and the new standard preparation of carefully mixed and dried digitalis has been thoroughly tested in comparison with the existing international standard. For strophanthus preparations also a standard is now available when required. Work on commercial samples of pituitary (posterior lobe) has also proceeded. Dr. Burn, with others, has investigated three actions of pituitary—namely, vaso-constriction, stimulation of uterine muscle, and a restraining action on excessive diuresis. Evidence has been obtained which seems to show that these three actions are produced by *three independent principles*. The National Collection of Type Cultures, accommodated at the Lister Institute, has again shown expansion during 1928–29. Over 5,000 cultures were distributed, and over 300 new strains were added to the collection. The work of the Standards Laboratory at Oxford, under the general direction of Professor G. Dreyer, has been maintained by Dr. A. D. Gardner and Miss E. I. Stubington, both in the whole-time service of the Council. There has been an undiminished demand for standardized cultures (suspensions) and serums. Special work has been carried out with reference to the H and O forms of typhoid and other bacilli, and excellent "O" suspensions of *B. typhosus* have been prepared from non-motile smooth variants by the broth-formalin method.

(To be continued.)

THE INTERNATIONAL TRAFFIC IN DANGEROUS DRUGS.

REVELATIONS FROM EGYPT.

[From a Correspondent.]

THE first annual report of the Egyptian Central Narcotics Bureau[1] reveals a condition of affairs regarding drug addiction in that country so bad as to be almost incredible. It estimates that no less than 4 per cent. of the population of Egypt are drug addicts. This figure is founded on censuses made over limited populations and on figures obtained from the prisons. The great majority of the addicts are young men, and hence the incidence among this class of the population must approach 10 per cent. The drugs used are heroin, hashish, opium, morphine, and cocaine, but heroin addiction is by far the commonest vice, for an interrogation of 200 addicts who were prisoners showed that no fewer than 138 used this drug. Addiction produces financial, physical, and moral ruin. The addict spends most of their wages on the drug, become physical wrecks, and commonly end in jail. The prisons of the country were built to hold 12,000, and now contain 24,000, of whom 7,000 are addicts.

The investigations of the Bureau have revealed that the drugs which are poisoning the Egyptian population are supplied by international organizations with branches all over Europe, which operate on a huge scale and make enormous profits. The nature of the profits is indicated by the fact that heroin, which is bought at £25 per kilo from the manufacturer, is sold to the retailers in Egypt for £85 per kilo, and is finally sold to the addicts for sums varying from £300 to £3,000 a kilo. The amount of heroin smuggled into Alexandria annually is estimated at two and a half tons; therefore the profits of the trade must run into millions of pounds annually. Two smuggling organizations, with centres at Vienna and Basle respectively, have been broken up by the efforts of the Narcotic Bureau. In connexion with the former case the Bureau discovered that one French factory in the Mulhouse district exported 5,016 kilos of heroin in the year 1927-28.[2] Curiously enough, the French official figures for the export

[1] Annual Report of the Egyptian Central Narcotics Intelligence Bureau for 1929. Government Press, Cairo.
[2] Loc. cit., page 5.

of heroin by the whole of France for those years only amount to 4,341 kilos.[1] This discrepancy raises a disquieting doubt as to the exact value of the figures on drug traffic that are supplied to the League of Nations. Both sets of figures are, however, considerably in excess of the total legitimate world need of heroin, which is not more than 1,500 kilos per annum.

The report is full of interesting details concerning the tricks by means of which the drug traffickers evade the law. In the first place the manufacturer employs all the resources of organic chemistry to evade such restrictions as are imposed by the laws of his country. A Swiss chemist carried on a lucrative trade for years by manufacturing a compound dionyl (acetyl propionyl morphine) which differed sufficiently from heroin (di-acetyl morphine) to evade the laws regulating the manufacture of the latter substance. The drugs are exported by gangs of skilled smugglers. Unfortunately they are peculiarly easy to conceal, and can be smuggled in a great variety of ways. In addition to such usual methods as trunks with false partitions, they have also been sent as portions of commercial consignments. Thus, in one instance, 1,000 tins of powdered glue were examined, and 24 of these were found to be filled with a heroin derivative; this discovery was only made by opening every tin in the consignment. After passing through the hands of the wholesalers in the big Egyptian cities, the drugs are finally peddled by retailers, who usually are themselves addicts.

This report deserves careful attention, because it is much the most complete and authoritative account that has yet appeared concerning the international traffic in dangerous drugs. Unfortunately the situation in Egypt is not unique, for something similar, but on a much larger scale, is happening in China, and, moreover, there is an extensive, although less intense, traffic in these drugs throughout most Eastern countries. As the report points out, Egypt and the Far East are being made the victims of the commercial greed of Europe, for the drug manufacturers of Central Europe are making huge fortunes by the wholesale poisoning of the Eastern populations. These countries are relatively helpless to protect themselves because the drugs are so easy to conceal, and the contraband trade is so lucrative that it is almost impossible to suppress it as long as the manufacture of the drugs is unchecked. There can be no doubt that it is the moral duty of the manufacturing countries to take the only step that is likely to suppress this traffic—namely, to put into practice the decision taken at The Hague in 1912, and at Geneva in 1925, and to limit the manufacture of drugs of addiction to the amount needed for medical and scientific purposes. This course is now being proposed by the Advisory Committee of the League of Nations, and it is a proposal that deserves the support of the medical profession throughout the world. In the first place, it is an obligation of honour, since it is the fulfilment of a promise made nearly twenty years ago. In the second place, it is the only way to check a great and growing evil that is becoming a fruitful source of international ill will.

All forms of State control are bound to involve inconvenience to individuals, and the rigid regulation of the sale of drugs of addiction is particularly inconvenient to the medical profession, which has to use these drugs for legitimate purposes. Fortunately for us, addiction to dangerous drugs is not sufficiently common in this country to make the urgency of the need for their regulation obvious to all, and hence the medical profession at home is apt to chafe at being cumbered with rigid regulations accompanied by severe penalties. It is important that the profession should realize that the chief purpose of these regulations is to check an evil which in other countries has grown to gigantic proportions, and which is naturally causing bitter resentment against Europe among the best citizens in Eastern countries. The Egyptian report makes unpleasant reading, but it is a relief to find that there is no hint that any of the smuggled drugs have come from this country. This suggests that the inconveniences that our medical profession has had to put up with in regard to these drugs have not been a useless sacrifice.

ROYAL MEDICAL BENEVOLENT FUND.

ANNUAL MEETING.

THE annual meeting of the Royal Medical Benevolent Fund was held at the House of the Medical Society of London on March 10th, with Sir THOMAS BARLOW presiding.

Sir PERCY SARGENT, joint honorary secretary, read the ninety-fourth annual report of the Fund, which recounted the steps taken to give greater publicity to the Fund's existence and work. The previous year's income from subscriptions and donations had been increased by over £600, and stood at £9,230. Gratitude was expressed in the report for the continued assistance given by the British Medical Association in collecting subscriptions from its members. The amount so collected during the year under review had been £1,590, and in addition £995 had been allocated by the Charities Committee of the Association (£169 more than the previous year). Reference was also made to a handsome donation of £630 from the Medical Insurance Agency. With regard to the distribution of funds, 416 grants had been voted, amounting to £8,639. From this sum 295 grants had been made to regular beneficiaries, who applied every year for renewal, and whose financial circumstances were annually reviewed. The remainder had been given in the form of single grants to assist persons in temporary difficulty, or as grants specifically for the purpose of education. Assistance of this latter character, amounting to £750, had been afforded to 21 applicants. The names of 191 annuitants were on the books, and the amount given in that form—namely, £5,437—was £621 more than during the year before.

Sir CHARTERS SYMONDS, the honorary treasurer, said that if the Fund were to close down that day it could meet all its liabilities and have between £700 and £800 in hand. The financial position had improved since October last, when it was feared that the income would not reach the previous year's figures, and that the amount of the grants would have to be limited. At the December meeting of the committee, however, money having come in in response to various appeals, it was found possible to vote grants without any reduction. A meeting of the vice-presidents had taken place during the year, with members of the committee, to discuss in what way greater support of the Fund might be obtained from the profession generally, and one good result of that meeting, at which several of the vice-presidents volunteered to give help in the way of personal influence, was that most of those who gave donations had become annual subscribers. He also mentioned the service in Liverpool Cathedral on St. Luke's day, when £113 was collected, and suggested that medical men in other cathedral cities might arrange for similar services to be held.

The officers of the Fund were all re-elected, with thanks for their services, and a former office was revived, that of chairman of the Case Committee, Sir THOMAS BARLOW remarking that the responsibilities of the Case Committee had increased of recent years, and it was never an easy task to adjudicate on some of the cases that came forward. It was therefore thought well to reconstitute the office of chairman of the Case Committee, and to nominate Dr. C. O. Hawthorne for that office. Sir PERCY SARGENT seconded the president's proposal, which was adopted unanimously. On the motion of Sir CHARTERS SYMONDS, seconded by Mr. BISHOP HARMAN, a number of vice-presidents were elected, including Dr. J. F. Walker, chairman of the Charities Committee of the Association, and Dr. Alfred Cox, Medical Secretary. Dr. Cox proposed the re-election of those members of the committee of management who retire by rotation, with one new member, Mr. Sampson Handley, to fill a vacancy; and the remainder of the proceedings consisted of votes of thanks to the honorary local secretaries, the medical and lay press, and others who had assisted the work of the Fund in various capacities. Sir THOMAS BARLOW made reference to the death of Sir Alfred Fripp, who had been a strong supporter of the Fund, and said how sincerely all the friends of the Fund sympathized with Lady Fripp, a member of the committee of management, in her bereavement.

Scotland.

Food Supervision in Scotland.

THE Department of Health for Scotland has issued a useful circular[1] dealing with the regulations bearing upon food. This is one of a series dealing with the effect of the Local Government (Scotland) Act, 1929, on health policy and administration. It is pointed out that in the past the public health local authorities have been concerned with food mainly through administration of the statutory measures directed towards (*a*) ensuring a pure food supply, and (*b*) the prevention of fraud on the part of the vendor, under the Public Health (Scotland) Act, 1897, the Regulations as to Food Act, 1907, the various Milk and Dairies Acts, and the Food and Drugs (Adulteration) Act, 1928. The department now points out that local authorities have also a direct interest in the wider problem of nutrition, especially in regard to the well-being of the school child and of the expectant and nursing mother. These subjects will now come within the province of town and county councils. Their attention is drawn to the provisions of the Public Health (Scotland) Act, 1897, which provided for the inspection of articles intended for food, and the seizure of food unfit for consumption; also to the Public Health Regulations (Scotland) regarding unsound food, overseas meat, and preservatives in food, issued in 1925. These regulations, it is pointed out, should be rigorously enforced. As regards milk supply, attention is directed to the Milk and Dairies Act, which came into force in 1925, providing for the appointment of veterinary inspectors by local authorities to conduct systematic inspection of dairy cows and of premises where milk is produced or handled; also to the various Orders under this Act regulating methods of storing and grading milk, the standards for condensed and dried milk, and the provisions for labelling them. The arrangements which the Department recommends for the veterinary inspection of dairy cattle are summarized, and it is urged that the sampling of milk for purposes of bacteriological examination should be at least as frequent as sampling for chemical analysis. In connexion with the licensing of tubercle-free herds under the grading system, the Department has directed that, from July 1st, 1930, the double intradermal test shall be the only one used in the tuberculin testing of cattle. With regard to the enforcement of dairy by-laws, the department considers that there is need for quicker progress in many county districts, and reminds the new authorities of their duty in regard to structural requirements and methods in dairies. It is pointed out that the Local Government (Scotland) Act, 1929, empowers councils to spend money on public health propaganda, and it is suggested that powers should be used to encourage a more extensive consumption of pure milk through popular lectures by medical and veterinary officers, circulars to medical practitioners on grading and milk supervision, and the supplying of milk to children from tubercle-free herds. The arrangements for meat inspection are also summarized; it is suggested that advantage might be taken of the extensive motor transport in the meat trade to use the facilities afforded by a conveniently located public abattoir rather than to retain a number of private slaughterhouses of various standards of efficiency and sanitation.

Eradication of Bovine Tuberculosis.

A scheme, which has been submitted to the Ministry of Agriculture, has been issued by the Scottish Branch of the *National Veterinary Medical Association* for the eradication of bovine tuberculosis. The association draws attention to the progress which has been made in America by the use of tuberculin and by slaughtering cattle giving a positive reaction, but considers that it would be impracticable to apply the American plan immediately by a widespread campaign in this country. It suggests that the appropriate scheme should be a voluntary one, and that a reliable test should be introduced to separate healthy from diseased cattle, so that the latter may be evacuated from the herd. If contiguous herds were treated in this way large tracts of country would be effectively cleared of bovine tuberculosis. A measure of compulsion might ultimately be applied to owners in intervening areas. Compensation would be given for the removal and slaughter of diseased cattle. The scheme proposes that applications should be invited from owners who wish to take advantage of the benefits conferred by it, and who are prepared to conform to the regulations laid down by the Ministry. It recommends that early preference should be given to herds owned by small holders in view of the great danger to the public from a cow with tuberculosis of the udder in a small herd. The tuberculin testing should be carried out by a practitioner selected by the owner. When he has tested the whole herd without finding a reactor a crucial test would be applied by a representative of the Ministry. If no reactor was then found, the herd would be certified by the Ministry. Reactors might be isolated in the first place, and afterwards slaughtered as far as the funds devoted to the scheme permitted. The scheme urges that an annual grant should be made for a period of years for these purposes. This grant would pay the cost of testing, compensation for reacting cattle, for disinfecting premises, and in providing temporary buildings for the isolation of reactors. In many cases owners or local authorities would be willing to bear part of the cost of eradicating the disease from their herds or districts.

Health Administration of the Future.

On March 11th, Dr. J. Parlane Kinloch, chief medical officer of the Department of Health for Scotland, addressed a meeting of the Institute of Public Administration, at the City Chambers, Edinburgh, on aspects of health administration. Mr. John Jeffrey, secretary of the Department of Health for Scotland, who presided, said that the new authorities about to be created would be less subject to Government control than those at present. In his address Dr. Kinloch referred to the Greek ideal of healthy individual life, and to the new attitude of public health authorities towards the care of the individual. Efforts to improve conditions of environment, however, had not slackened. They were still striving to remedy evils of the slums, overcrowding, unhealthy dwellings, pollution of air and streams, deficiencies of diet, unsound and adulterated food, contaminated milk, insufficient and impure water supplies, and lack of sanitation. The health services had gradually lengthened the average span of life, from 20 years in the sixteenth century to 25 years at the close of the eighteenth century, to 47 years in 1910, and to 56 years in 1928. These figures, he said, implied much more than that the average duration of life had been doubled, for that life was more vigorous for the people as a whole. The history of public health showed that if we knew enough and could apply our knowledge, every child might enjoy a healthy life till old age. They were approaching this ideal. The Local Government Act of last year, he said, created a framework into which the unrelated services of the past would be fitted; the benefits should be enormous. It might seem to some that it was a defect in organization to have left the national insurance medical service outside the jurisdiction of the local health authorities, but the two great services were in process of being co-ordinated. The body of general family practitioners, who would continue to be the backbone of medical service in the country, could be brought into intimate contact with the new health machinery. A comprehensive domiciliary medical service could best be obtained by extending the insurance principle to the dependants of insured persons. It might possibly be further extended to classes of people like small shopkeepers who had not hitherto come within its scope. As a logical outcome of the hospital clauses of the new Act, the local authority in co-operation with voluntary hospitals would provide an institutional and specialized medical service for the whole community. Payment for such service would be made according to a person's means. *Money* should be spent rather in cutting off disease at its source than upon treatment. There should be further provision for research. With a total commitment of £10,000,000 or £20,000,000 on health services in Scotland, the two departments which were responsible for research were spending less than £10,000 a year on this service. On the other hand, with a total

expenditure of about £1,000,000 on agriculture the State had considered it necessary to spend about £70,000 on agricultural research. It was a matter of social and national economics. If the country increased its expenditure on research it would be repaid in large dividends.

Edinburgh Housing and Hygiene Exhibition.

The exhibition of housing and hygiene organized by the public health committee of the Edinburgh Corporation for sixteen days was opened on March 12th by Mr. J. C. Watson, Solicitor-General for Scotland. Lord Provost Whitson, who presided at the opening ceremony, congratulated Dr. William Robertson upon his success in arranging the exhibition. The Solicitor-General said that the fundamental capital of any country was the strength of character, of body, and of mind of its citizens. While wars in the past had left a legacy of disease, the public health administration and the medical services had prevented this occurrence after the late war. He suggested that there should be closer contact between the thinking mind of medical schools and the trained minds and exhaustive records of public health departments. If this collaboration were brought about, the experience gathered by the public health department could be used to direct and guide the research of academic workers whose experiments could be tested in the organization of the public health department. In referring to the exhibition, the speaker remarked on pioneer work that had been done in Edinburgh in cultivating a social responsibility. Over 120,000 persons visited the ten days' exhibition held two years ago; it is expected that the present exhibition will be even more successful. One of the exhibits is the simplest form of new house built by the Corporation Housing Department; as a contrast a reproduction is shown of a one-roomed slum house at present being removed under improvement schemes. Bad features of one-roomed houses, back-to-back houses, and other condemned property are indicated by plans and photographs. The Corporation Maternity and Child Welfare Department has an exhibit showing welfare clinic rooms and necessary equipment. Another shows the facilities available for protecting the pre-school child from diphtheria. A day nursery illustrates the municipal facilities offered for the day care of infants and toddler children. There is a child-garden for mental and physical development, and artificial sunlight clinics equipped with lamps. A private company gives demonstrations of the process employed in the production of irradiated tubercle-free milk. Numerous working exhibits are on view, including a model laundry, a model bakery, the preparation of pasteurized milk, and other methods of preparing food and substances in general use. A stall is devoted to food and dietetics; practical lessons are given on simple cooking by smokeless fuel, and short talks on food problems.

The Ideal Hospital.

In an address to the Edinburgh Women Citizens' Association on March 11th, on the requirements for the hospital of the future, Dr. William Robertson, M.O.H. for Edinburgh, said that Edinburgh had fallen behind Glasgow in providing modern hospitals for the treatment of the sick poor. In Glasgow some of the institutions erected by the parish council were of the same standard of construction and equipment as the best of the Scottish infirmaries. There were some councillors who thought there was a danger of local authorities, such as those in Edinburgh, trespassing on the work of the voluntary services, but some years would elapse before any municipal hospital would be ready to receive patients in Edinburgh. Dr. Robertson then discussed the best design for a hospital. Was it possible to devise something better than the long corridors with side passages and counter-crossings which caused administrative difficulties and took up much valuable space? He thought that the hospital of the future must be surrounded by large grounds, not only for possible future extensions, but also to ensure free circulation of air and liberal exposure to sunshine. A hospital should be arranged on a pavilion plan, with pavilions of one or two stories. The best arrangement was the butterfly principle, where the wings were wards, the body the administrative quarters, and the tail provided smaller wards or rooms for the isolation or nursing of special cases. Such pavilions would be dotted over an extensive site, and might be interspersed with flower-beds and well-kept lawns. It was of the greatest importance in hospital construction to provide means for free irradiation by the sun.

Ireland.

Treatment of Tuberculosis.

In presenting the annual report of the Newcastle Sanatorium, co. Wicklow, Professor T. Gillman Moorhead, M.D., referred to the fact that treatment with a salt of gold had been carried out in a number of cases during the past two years. This treatment had been introduced in Denmark about four or five years ago, and consisted in the injection of sanocrysin into the blood, with the object of destroying the bacillus of tuberculosis without affecting the body of the patient. Up to the present fairly good results had been obtained, but the treatment was still only experimental. Professor Moorhead also referred to the establishment of a tuberculosis colony in connexion with Peamount Sanatorium. He hoped that the colony would not be reserved for the exclusive use of patients treated in a single sanatorium, and that facilities would be given to patients from other sanatoriums to enter the colony as soon as possible. A single colony for the whole of the Irish Free State was likely to progress more satisfactorily at first than separate colonies attached to each sanatorium. Sanatoriums had solved the problem of immediate treatment of tuberculosis; well-managed colonies would do much to solve the problem of after-treatment. He thought that the appointment of tuberculosis officers in every county in the Free State would be of great assistance in early diagnosis, and in introducing a more systematic home treatment through trained health visitors. The average results obtained last year at Newcastle Sanatorium were as follows: in Group I there were 26 per cent. apparent cures; 15 per cent. were much improved, and 13 per cent. were improved. If a thorough system of after-care were established, the majority of these patients could be maintained in good health and fair working capacity for many years. Facilities were now available for post-graduate teaching in the sanatorium.

Dublin's Radium Supply.

At the recent annual meeting of the Royal Dublin Society Professor John Joly, F.R.S., the president, said that the society had less radium at its disposal than had many second-rate London hospitals, although it was the principal source of supply in Dublin. The society is appealing for £5,000 for the purchase of radium, and has undertaken to give pound for pound on all money subscribed.

England and Wales.

Radium Department at North Middlesex Hospital.

THE Minister of Health (Mr. Arthur Greenwood, M.P.) visited the North Middlesex Hospital, an institution under the control of the Edmonton board of guardians, on March 18th, to perform the double function of opening a new department for the treatment of cancer by radium and of laying the foundation stone of an extension of the nurses' home. The hospital possesses rather more than 500 milligrams of radium, and an excellently equipped department has been created for its utilization. The building, detached from the main hospital, consists of a reception room, with dressing cubicles for patients; a radium record and issuing room, with a specially designed indicator board for records of radium tubes issued; a strong room, containing a radium safe weighing one and a quarter tons and giving seven inches of solid lead protection in all directions against the action of radium; a treatment room, and a radium work-shop, with special lead-protected benches on which radium needles are handled and made up into silver containers. There is an excellent installation of electroscopes and other apparatus for

detecting and recording the radium content. An adjoining building houses the x-ray treatment department, which includes an apparatus for deep therapy. The walls of this room are lined with sheet lead one-quarter of an inch thick, and the operator controls the apparatus from a cabin outside. The present extension of the nurses' home provides for 100 beds (in addition to the 105 already in use), together with lecture and demonstration rooms, dining room, and offices, and the idea is to accommodate the whole of the large staff of nurses for a hospital which had 10,000 in-patients last year, and to provide them with comfortable home-like surroundings, with every benefit of proper rest and recreation. The ceremony was made rather the occasion of a "swan song" on the part of the guardians, several of whom have held office ever since the hospital was opened twenty years ago. Mr. E. E. Metivier, the chairman of the board, after referring to the fact that the opener of the hospital in 1910, Sir William J. Collins, was in the present company, gave a sketch of the hospital's noteworthy growth, and the increasing provision it had made of facilities for the neighbouring local authorities. Dr. Spencer Mort, the medical superintendent and surgical director, explained the purpose of the new radium department, after which the Minister of Health paid a warm tribute to the board of guardians and the staff for having transformed what was once a workhouse hospital of the old type into a first-rate modern institution. Before handing over the control to a different body, the guardians had crowned their work by the establishment of the new radium department. It was perhaps fortunate that this scheme was on its way before the late Government appointed the committee to consider the allocation of radium, for it meant that the Edmonton guardians had succeeded where perhaps, had they tarried a little, their path might have been more difficult. It was a matter of pride, the Minister considered, that the guardians should have been so early in the field with this modern treatment, and he believed that the new centre would be a model for local authorities in other parts of the country. After referring to the need for ensuring to nurses as many of the amenities of home as were possible, Mr. Greenwood touched on the approaching extinction of the guardians. It was natural that there should be a tinge of sadness in the air, but he believed that everybody appreciated that in the long run the coming change would work out for the public good, and at least the board of guardians at Edmonton could relinquish their work with the knowledge that they had created something which would be a valuable inheritance for their successors.

The Institute of Ray Therapy.

The Institute of Ray Therapy (Sunlight Clinic) in Camden Road, which was the subject of a descriptive article in these columns on January 25th (p. 163), was opened by the Lord Mayor of London (Sir William Waterlow), who was attended by the Sheriffs, on March 13th. Mr. Alfred T. Davies presided over the ceremony, and in some introductory remarks expressed the indebtedness of those concerned in the work of the institute to Mr. G. F. Kimber, who had paid to the account of the trustees the generous sum of £10,000. The institute had an excellent advisory council, and the equipment was the most modern in England. The council felt that with the co-operation of the trustees and Dr. Beaumont as medical director the institute would be of immense benefit not only to St. Pancras but to the whole of London. Sir William Hale-White, president of the medical advisory committee, said that the object of the institute was to enable people of small means to obtain up-to-date light treatment. No one would be asked to pay more than he could afford, and necessitous cases would be treated free. Further, no patient would be admitted except on a medical certificate signed by his own doctor, and any person who had means which enabled him to pay for private treatment would have no right to attend at the institute. A special certificate had been provided for the signature of the doctor sending the patient, and the doctor would mark on it the grade according to which the patient should be charged. The minimum for those who could pay would be one shilling per treatment, and no one would be asked to pay more than five shillings. Sir William added that apart from the financial provision, the promoters owed everything to Dr. Beaumont, who designed the building, and with the help of Mrs. Beaumont, the honorary secretary, launched the organization. The Lord Mayor, in declaring the institute open, said he understood that an important function of the institute would be to place light therapy on a sound scientific basis and estimate its capacity for good, while at the same time providing beneficial treatment for patients who were not in a position to obtain it elsewhere. He was impressed by the names of the members of the medical advisory committee, which included representatives of two Divisions of the British Medical Association. He believed the new institute to be in line with the progress which was being made in other countries in the light treatment of deficiency and other diseases, and the aim of the Camden Road centre was to be a "poor man's Riviera," where those who were ordinarily denied the invigorating effects of sunlight for the treatment of complaints which were due to or accelerated by light starvation might obtain a renewal of health and energy. Mr. Kimber, the treasurer and benefactor, in proposing a vote of thanks to the Lord Mayor, said that the origin of the whole scheme was a lecture by Dr. Beaumont at the St. Pancras Rotary Club two years ago. He was impressed by the account given by Dr. Beaumont of the benefits to be derived from light treatment, and especially by his remark, "If we only had the money there is no telling what we could do." Professor John Eyre, a member of the medical advisory committee, seconded the vote.

Middle-class Clinics.

At the annual general meeting of the National Baby Week Council, held on March 12th, with the Hon. Sir Arthur Stanley in the chair, a brief discussion took place on a subject announced as "The extension of the knowledge of parentcraft to parents whom the existing welfare services do not reach"—in other words, the establishment of baby clinics for the middle and upper middle classes. Dr. Harold K. Waller, medical officer of St. Katharine's College, Poplar, and of the Babies' Club, Chelsea, advocated the establishment of clinics to which persons would, on payment of a subscription, be entitled to go for advice. If such work was to be extended among the middle and upper middle classes, it was important that it should secure the good will of the medical profession, and it must be made clear that the work was to be confined to the giving of advice as regards the prevention of disease, and not to embrace treatment. He felt that those who stood in the social scale just above the class visited officially by the health visitor were most in need of baby clinics, for very often they lacked the sense of parentcraft which had been gained by those in a different class of society. The money spent on the extravagant decoration of nurseries and on elaborate perambulators would be better spent on a subscription to a clinic where advice could be obtained on the supervision of the baby, a matter which people were apt to regard, until difficulties arose, as coming by instinct. After Mrs. Eva Hubback, of the National Union of Societies for Equal Citizenship, had spoken on the same lines, Mr. E. B. Turner put forward the view of what he called a confirmed individualist. He was not in favour of the proposal, disliking, he said, this mass treatment. The existing centres had certainly done good work, but he thought it would be a mistake to extend the system to a class of patients who were able to go to a private doctor. His own feeling was that parentcraft could be taught much better by the family doctor than at a clinic, where work would tend to become stereotyped. Dr. D. H. Geffen, medical officer of health for Enfield, said that Mr. Turner was not looking at the matter from the right point of view. The main point was the well-being of the mothers and children. If that could be secured by the establishment of clinics, the interests of the profession were of comparatively small importance, and he believed most practitioners would rejoice in the result. The clinics would certainly increase the work of the general practitioner in one direction, for disease would often be detected in its early stages and the cases be sent to doctors. Mr. Turner said that Dr.

Geffen had mistaken the bearing of his remarks. They had not been in any way directed to protecting the practice of the general practitioner. He had had in view the health of the mothers and the children, which he believed could be better looked after in the houses than at clinics. Mrs. Newman, speaking as chairman of a centre committee, said that one-half of the mothers dealt with did not know when the babies were ill, and one respect in which the centres did good work was by informing a mother of the state of the case and sending her off to a medical man. She even thought it would be a good thing if an arrangement could be made in districts like her own (Hampshire) for paying mothers to attend the clinics once a week.

Central Midwives Board.

The Central Midwives Board for England and Wales met on March 6th. A penal session was held, followed by the ordinary monthly meeting. The following re-elections to the Board were announced: Miss Edith Greaves, Miss Ada Davies, Dr. William Allen Daley, Mr. A. B. Maclachlan, Mr. Victor Bonney, F.R.C.S., Dr. R. A. Lyster. Intimation was given of the following resolution passed by the Gloucester City Council:

> That the council be recommended to support the Minority Report of the Departmental Committee that, subject to the improvement of certain of the existing arrangements of the Central Midwives Board, the powers of approval of training institutions and teachers and of the framing of the rules as to training should remain with the Midwives Board.

The Cornwall County Council also had notified its concurrence in the Board's view that it would be undesirable to transfer the power of approval of teachers and training institutions, and of the framing of rules as to training, from the Board to the Minister of Health. It was resolved to reply to an inquiry from the town clerk of Kensington: That, while the Board fully appreciates the value of the treatment and advice given at ante-natal clinics, it does not deem it advisable to compel midwives to take or send their patients to ante-natal clinics.

Correspondence.

RESEARCH IN MEDICINE.

SIR,—The article on research in medicine, by Sir Thomas Lewis, in your last issue, contains so much that is true and suggestive that it is a pity he has not been able to speak less disparagingly of the clinicians. It may be that these poor men are "unreliable in the clinical statement of fact," that they have a "less rigid standard of truthfulness than the physiologists," "make statements without evidence," and are "superficial" and "without any real grasp of the problems set by disease." I do not doubt that their "easy and uncritical acceptance of statement of fact and hypothesis" will induce them easily to accept this diagnosis of their condition, but, after all, they are doing their best. Their "observational" methods may be slow and not as productive of results as we all could wish, but it is rash to say that they are played out. The clinician is the field naturalist of medicine, and there are still new diseases, fresh types of disease, and novel "symptom-complexes" to be described and unravelled. (One has only to think of epidemic encephalitis and "pink disease" as examples in the last few years.) Everyone will agree that the experimental method of investigation is the most satisfactory, but the difficulty is to apply it in the clinical field. We cannot really treat patients in a ward as the physiologist does rabbits in a laboratory, and I fancy that the most enthusiastic "research physician" would find himself becoming by degrees "preoccupied by solicitude for his patient" when constantly brought into contact with sick folk in a hospital—at least I hope so.

In any case, is Sir Thomas Lewis really sure that even the experimental method would be best applied by the type of worker he wishes to bring into existence? Surely to train a man for research only, to cut him off from all vital contact with students, and to disinterest him in questions of diagnosis and treatment is the most certain way to narrow his outlook and to sterilize him for the very purpose for which his post was created.—I am, etc.,

London, W.1, March 18th. ROBERT HUTCHISON.

SIR,—I have read with deep interest Sir Thomas Lewis's considered remarks on the present position and needs of medical research in this country. I am sure that all who are concerned for the future of what he calls "progressive medicine" will feel grateful to him for his fair and able exposition of the problem. With his main thesis—the impossibility of combining successfully the practice and teaching of curative medicine with experimental clinical research—there will be general agreement. But some of his statements call for comment, and some of us must beg leave to doubt the full practicability of the remedial measures under consideration by the Medical Research Council as at present forecast.

Speaking of diagnosis as a function of the practising physician Sir Thomas says: "A diagnostician goes into his wards with one chief goal in view—it is to place a label correctly, to say that here is a species or subspecies that someone has described, its name being this or that." This is surely putting a very narrow interpretation on the word diagnosis, and one which can scarcely be accepted. For the judicial and conscientious physician diagnosis implies, as its derivation signifies, the *through or thorough knowledge* of the patient and his disease. This involves an appreciation of the influences of heredity and environment, of physical type and personality, of the meaning of symptoms, and of the value of objective findings, whether made at the bedside or in the laboratory, and includes, finally, that very endeavour to "know more" which is claimed as the purpose of the researcher. Some of the best and most accurate and useful diagnoses are made without a label being affixed at all. Now, unless he can acquire by long observational training some aptitude for diagnosis in this fuller and better sense, I would maintain that a "research physician," however well trained scientifically, will seldom have sufficient knowledge and breadth of vision to produce work of prominent value. Disease cannot be studied apart from man. Disease affecting one system can only rarely be investigated properly without the study of other systems. It is upon attempts to do this that most of the faults and shortcomings of specialism depend. We should think carefully before appointing, in the person of the research physician, a new variety of specialist, and if we decide upon the appointment we should endeavour to ensure that his preliminary clinical training is both long and general. His aim may be collective diagnosis, but the study of individual diagnosis is an essential part of his education.

Pursuing his argument that the research physician must be largely relieved of the onus of diagnosis and treatment, Sir Thomas says, ". . . it is to be realized that no investigator can be successful who allows, or is forced by circumstances to allow, solicitude for his patients to preoccupy his mind," although later he insists that the workers must have full medical charge of their material. This seems to me contradictory and unsound. Without considerable and constant solicitude for the patient there can be no deep understanding of disease. Even in animal experiment this is apparent. There have, I imagine, been few finer examples of well-conducted and productive research than Pavlov's work on digestion and on conditioned reflexes. It is abundantly clear that these painstaking experiments would have been useless had not Pavlov and his associates exercised the greatest solicitude in the handling of the animals. It was necessary for the success of the work that the dogs should be treated carefully, even affectionately, that their individual temperaments and their physical and psychological reactions should be intimately studied and understood. How much more essential, if we except the case of some very localized types of disease, is such solicitude in the investigation of the more complex human organism! Furthermore, under the conditions suggested, how are the patients to be found? Can we expect that institutions will show themselves willing to allocate patients to a physician with whom diagnosis and treatment are not to be a main concern?

Once more, speaking of the practising physician, Sir Thomas says: "His solutions are reached in by far the greater number of instances by no process of logical reasoning, but upon the basis of previous experience or upon the basis of what we call intuition, a faculty often remarkably developed." I would suggest that there is no such thing

as intuitional diagnosis. The physician or his pupils may not always be able to retrace the steps whereby an able opinion has been reached; but I believe that the real basis of such opinions has always been careful observation of other cases, a working knowledge of human physiology, anatomy, and pathology, and a logical induction from the information which these provide, or, in other words, the application of those very qualities which it is so necessary to foster in the research student. Harvey and Mackenzie both combined the observational with the experimental method, and recognized that the two were complementary. The observational method, to be fruitful, requires contact with large numbers of patients, preferably under varying conditions of life and environment, and not only in a hospital ward. There is great need, all will agree, for more and better scientific method in clinical medicine, but it should also be remembered that those functions of the body which can be studied separately in an experimental way and by accurate methods are at present few.

Sir Thomas Lewis has been rightly quoted as an outstanding example of the research physician, and his work is an abiding testimony to the soundness of the principle of liberating good men from the necessity of practice in order that they may the better devote themselves to important work. It seems to me, however, that in quoting this example the Medical Research Council have not made sufficient allowance for particular circumstances. In the first place, their man is an altogether exceptional man, scientifically minded, and also with the experience of practice behind him; and secondly, it so happens that his researches have dealt with a branch of morbid physiology susceptible of study by a precise physical method. At the moment there is little indication that other morbid functions can be approached in so separate a manner and by methods so precise as those which have been employed in the study of normal and abnormal cardiac rhythm.

While, therefore, there is much in the idea of the trained research physician which must appeal to us all, there are many difficulties to be faced and some preliminary questions to be answered. Among these I would ask: (1) How and where is adequate material for the training and the research to be collected? (2) Given the material, how can curative and experimental medicine be divorced (or reconciled)? (3) How, at an early stage, are young men to be selected who will be found later to be suitable by temperament and mental equipment and at once sufficiently skilled in the methods of science and logic and sufficiently broad-minded for a task which must frequently present far greater difficulties than those already encountered in physiological and pathological research? (4) How can it be ensured that clinical research shall be organized so far as possible on profitable lines? To-day a vast amount of time, money, and labour is being expended upon isolated researches which from the very nature of the problems undertaken can have no useful end; at the same time important fields are being altogether neglected.

With a view to discovering answers to these questions, and before there is new expenditure of funds, it would be interesting to hear the views of our leaders of medical thought, of men who, although they are compelled to practise and to teach, have made medicine their life's work and are familiar with its needs. It is curious that, with the exception of Professor Elliott, whose chief distinctions have been in physiology and academic fields, the Medical Research Council includes in its number no single representative of general or special medicine. There is the more need on this account that they should hear the voice of those who live in the midst of the problems and who feel the same anxiety to see them more wisely and intimately explored.—I am, etc.,

London W., March 17th. J. A. RYLE.

PEPTIC ULCER.

SIR,—May I join with Lord Moynihan in congratulating Dr. Arthur Luff on his valuable report on the collective investigation of cases of peptic ulcer. It is a most valuable piece of work, for which the thanks of all members of the Association are due to its author.

In his admirable review of the report (*Journal*, March 8th, p. 459) my friend Lord Moynihan with gentle touch reproaches me for my advocacy of gastro-jejunostomy in the treatment of gastric ulcer. I do so because, like Lord Moynihan in the past, I have found it to be eminently satisfactory. In the series of cases under review posterior gastro-jejunostomy gave only 50 per cent. of good results, and Lord Moynihan expresses surprise that the results are even so satisfactory. I share that surprise when I note that the appendix was removed only in 29.6 per cent. of the cases. This vestigial organ is so frequently a focus of infection that I regard it as futile to perform a gastro-jejunostomy unless the appendix is removed at the same time.

Lord Moynihan emphasizes the supreme importance of medical treatment and a proper dietary after operation. This cannot be reiterated too often, for I am convinced that a very large proportion of the failures after gastro-jejunostomy are the result of neglect of this vital factor. He also pertinently remarks that "individual rather than collective opinions will surely continue to control our thoughts and actions." I prefer gastro-jejunostomy to partial gastrectomy, save in exceptional cases, because it is a less severe and less mutilating procedure, and because in my experience, if the operation be properly performed, and provided the patients adhere to a reasonable diet, good results follow in over 90 per cent. of the cases. This must have been the experience of Lord Moynihan in the past, for in 1908 he wrote: "I am a sanguine advocate of this operation (gastro-jejunostomy), than which there is in all surgery none more completely satisfactory." If this were true then, as I have no doubt was the case, it is surely true to-day. *Nihil tetigit quod non ornavit*; I am confident that in Lord Moynihan's skilled hands either gastro-jejunostomy or partial gastrectomy will give highly satisfactory results. As he so truly says, the operation of partial gastrectomy has the advantage of difficulties. He prefers the "great adventure"; I, while admitting that the mortality rate of partial gastrectomy is not greatly higher than that of gastro-jejunostomy, prefer the less adventurous as being safer and no less sure.

I do not think the cases so admirably tabulated by Dr. Luff can be used to support Lord Moynihan's contention that the results of partial gastrectomy are better than those of gastro-jejunostomy. In the cases under review, the mortality rate of posterior gastro-jejunostomy with excision or infolding of the ulcer is 4.6 per cent., while that of simple gastro-jejunostomy is 11.4 per cent.,—that is, the mortality of a simple gastro-jejunostomy is two and a half times as great as posterior gastro-jejunostomy with excision or infolding of the ulcer, and about twice as high as that of partial gastrectomy. In other words, the part is greater than the whole, which, as Euclid would say, is absurd. The inference is irresistible, that the more severe procedures were performed by the "surgical Bobby Joneses," while the simpler procedures were mainly the work of the long handicap men. If this be so, then it is not fair to claim that the late results of the long handicap men are comparable to what can be achieved by the scratch men. Lord Moynihan cannot have it both ways. He says that the mortality rate for all types of operation is too high. If this be premised, then he cannot use the late results in this series to support his contention. It is clear that Lord Moynihan himself agrees with this view, for he writes, "Too much reliance must not be placed upon these figures; for a difference in the skill and competence of the surgeons concerned in the treatment of each group may be enough to account for differences in the figures."

I doubt whether the difference of opinion between us is as fundamental as would appear. Reading between the lines, I judge that Lord Moynihan has still a very warm corner in his heart for gastro-jejunostomy. It is my hope and belief that he will live long enough to return to his first and early love, which has served him so well in the past, and in the perfecting and popularizing of which he played such an important part.—I am, etc.,

London, W.1, March 13th. HERBERT J. PATERSON.

DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.

SIR,—The comments on my address published in the *Journal* of March 1st (p. 376) have raised some points of general interest.

I should like to thank Dr. Rose Jordan for her letter (March 8th, p. 466), and to say that I can endorse the two practical points there emphasized—the importance of firm pressure by the plexímeter finger, and the help it may be to have the patient breathe with the mouth open.

If Dr. McNeil (March 15th, p. 515) considers that my quotation from his article on the von Pirquet test in any way misrepresented his views I am extremely sorry. The burden of my argument was that the Pirquet reaction may be negative in an actually tuberculous condition. This Dr. McNeil admits. In spite of that admission, he concludes his letter thus: "The principal value of the test is when, having been performed by a correct technique, it is negative; in such cases tuberculous disease can be excluded." There is here no qualifying phrase: no suggestion that "although rarely," a serious error of diagnosis may result. It is a definite assertion which, on Dr. McNeil's own showing, is fallacious. That is the crucial point.

Dr. Weatherhead (March 15th, p. 516) quotes Clive Riviere on tuberculin tests in general, but does not get down to the bed-rock difficulty in the Pirquet reaction—the presence of a negative test in a tuberculous subject. He is all out for "the only tuberculin test which is now commonly held to have any real diagnostic value—namely, the subcutaneous test." By the time the practitioner has kept a careful three- or four-hourly record of the temperature for some days and finds that the mouth temperature does not rise above 99.2 F., and then understands from Dr. Weatherhead that "even this is running the risk of a dangerous focal reaction," he will be exercising only common-sense precaution if he refuses to touch this test at all.

I admit that to pass an opinion on the value or otherwise of ultra-violet light in pulmonary tuberculosis is liable at the present time to induce in some quarters rather strong reactions, and I have no doubt that Dr. Weinbren (March 15th, p. 516) can show reasons for the faith that is in him. All I can say is that the high priest in this particular temple is, I fancy, Dr. C. H. Würtzen, consulting physician to the Finsen Light Institute, Copenhagen. I have sat at his feet and done what in me lay to evaluate his results. This particular factor in treatment is obviously difficult to isolate and assess, but I do not think that the judgement I expressed, that its value is "very problematical," erred on the side of strictness.—I am, etc.,

Gloucester, March 17th. W. ARNOTT DICKSON.

DISADVANTAGES OF SANATORIUM TREATMENT IN WINTER.

SIR,—Dr. Arnott Dickson (*Journal*, March 1st, p. 376) draws from a deep well of experience in writing of tuberculosis. I wish he had given us one more bucketful and told us of the futility, sometimes even cruelty, of submitting advanced but chronic patients to the winter conditions of a sanatorium as usually arranged. Three factors cause the evil to continue: (1) Lack of other accommodation of a more suitable type. (2) The urgent need to "do something" for patients found in overcrowded homes, or with inadequate care available. (3) The pathetic trust of the average patient that the "doctors know best" and that his part is to "stick it." He realizes also that the assets of good food, good care, and good fellowship go far to counteract the discomfort.

Two solutions of the problem are possible. Central heating should be installed, in a part at least, of every sanatorium. (The whole of the institution which Dr. Dickson controls has been heated.) Some of the Poor Law infirmaries that will be available shortly for local authorities should be utilized as tuberculosis "hospitals" for chronic cases. To achieve reform, however, there must be a more general realization that the present system is not desirable.—I am, etc.,

Peppard Common, Oxon., March 11th. ESTHER CARLING.

OPERATIVE DEATH RATES AND PROFESSIONAL OPINION.

SIR,—A perusal of Sir John Thomson-Walker's admirable third Lettsomian Lecture, in which he shows that the general operative mortality of prostatectomy is just on 20 per cent., has set me wondering how it is that a death rate as high as this should be accepted by the profession with relative equanimity when a similar death rate in the case of Wertheim's operation for cancer of the cervix evoked much adverse criticism. It is the more puzzling because prostatectomy is carried out for a disease not necessarily fatal to life if unoperated upon, whereas Wertheim's operation is performed for a disease the mortality of which, untreated, is cent. per cent. It is true that death rates much lower than 20 per cent. have been recorded for both operations—for instance, that of St. Peter's Hospital, London, of 9.9 per cent. for prostatectomy, and my recent figure of 8.1 per cent. for Wertheim's operation—but these do not affect the question I raise.

It may be argued that prostatectomy cures those whom it does not kill, or a large proportion of them, whereas Wertheim's operation only cures (meaning by that five years' survival) 50 per cent. of those recovering from the operation, but I think the real explanation of the different attitude that obtains towards these two operations lies in the fact that one is carried out on men and the other on women, and that sentiment therefore weights one scale. I am very far from complaining of this, but it is interesting to speculate whether the scales would be weighted differently if women instead of men made up the bulk of the profession.—I am, etc.,

London, W.1, March 15th. VICTOR BONNEY.

RETROGRADE NEEDLING.

SIR,—Dr. Pridie in his article on March 1st (p. 389) indicates several points in radium technique which are not sufficiently appreciated. The ease with which radium needles can be inserted into the tongue through the floor of the mouth makes one wonder that this method of *approach, especially for cancers at the base of the tongue*, is not more commonly employed. In the *Medical Press and Circular* of December 8th, 1915, I described "direct needling" of the tongue by this route. The length of my platinum needles is varied by screwing extension pieces into the radium-containing barrel; different areas are radiated by pulling out the elongated needles, which are marked in centimetres, and shortening them as required. I bury threaded short radium or radon tubes and needles with the aid of a trocar, cannula, and ramrod. Radiating several areas by one insertion of a needle, besides being economical, is less severe on the patient.—I am, etc.,

Dublin, March 16th. WALTER C. STEVENSON.

OPERATION FOR VISCEROPTOSIS.

SIR,—Mr. W. H. Carson's paper on indigestion from the surgeon's standpoint (March 8th, p. 429) was interesting, but I would like to ask him a question with regard to his statement that "visceroptosis is not a disorder likely to benefit from surgery." Has Mr. Carson personally performed the "anchoring operations" which he condemns? If so, has he followed up his cases over a considerable period? If he has, it would be interesting to see his figures; if he has not, one cannot think that he is justified in his statement.

There is a prejudice against anchoring operations, no doubt because many types of operation are not successful; but my experience, and that of others, is that Waugh's operation performed conscientiously gives good results. Carslaw's article in the *British Journal of Surgery* of April, 1928, gives results over a period of seven years which are eminently satisfactory. The statement that these operations are of no use seems founded more on tradition than on scientific investigation of the facts.

Mr. Carson also takes the common course of blaming the patient for undergoing a series of operations. Surely the people who perform the operations are more to be blamed! Either the patient is a genuine neurotic and should never have been operated upon—a rare type, I

venture to suggest—or the right operation has not been performed, and the patient still seeks relief from symptoms from which she genuinely suffers. Anyone who takes up the question of visceroptosis from the surgical standpoint seriously will have patients of this type, whom an appropriate fixation operation has cured, both of physical and of mental symptoms.

I shall probably be asked for my figures, but I do not consider two years justifies publishing them as yet. My results, however, have compelled me to continue operating for visceroptosis, and I continue to have cases referred to me for operation by the general practitioner, who is in a very fair position to judge of results.—I am, etc.,

Southsea, March 10th. O. STANLEY HILLMAN.

ANAESTHETICS FOR SHORT OPERATIONS.

SIR,—I think most anaesthetists will endorse the opinions expressed by Dr. Rawdon Smith in the *Journal* of March 8th (p. 467). My personal experience of chloroform in dental extraction, especially when given in the semi-upright position, has been most unfavourable. On one occasion the patient collapsed from heart failure and had to be laid flat on the floor. I have seen the same thing in operations for circumcision, and well remember a narrow escape from a tragedy by holding the infant by the feet with the head downwards. As far as my observation goes no one in the present correspondence has mentioned as an anaesthetic chloroform and ether in equal parts. It will be found an ideal one; children take it well and it is easily administered by the open method on a Schimmelbusch mask.—I am, etc.,

King's Tamerton, Plymouth, March 12th. H. W. WEDDER.

OESOPHAGEAL OBSTRUCTION IN CHILDHOOD.

SIR,—In the *British Medical Journal* of March 8th (p. 467) there appeared a letter from Dr. Beatty criticizing an article by Dr. Ogilvie and myself in a recent number of the *Archives of Disease in Childhood* (1929, vol. 4, No. 24, p. 347); I should be glad if you would give me an opportunity of replying in your columns to his criticism.

In gathering together the clinical data of 12 children who had obstruction of the oesophagus, it was found that the symptoms and signs were remarkably similar. In 10 cases the similarity was further enhanced by the *x*-ray appearances, which showed that the obstruction was situated at the junction of the middle and lower thirds of the oesophagus, opposite the level of the seventh thoracic vertebra. In the other two cases the obstruction was at the level of the diaphragm. The clinical picture was sufficiently uniform to suggest that a common pathological process accounted for these cases. Post-mortem evidence was available in 4 instances, in 3 of which death occurred during the height of the symptoms. In 1 the oesophagus showed narrowing without fibrosis at the level of the diaphragm, and in the other 2 there was a fibrous constriction in the oesophagus; in the fourth child, who had been free from symptoms for a year before death, and who died from a different condition, the oesophagus was found to be normal.

In searching for an explanation of these cases we suggested that the original defect in the oesophagus was one of inadequate growth, which could right itself in time by the growth of the parts, provided that the level of narrowing was not injured in some way, such as by the passage of bougies. Surely if this explanation was correct one would expect the oesophagus to appear normal a year after the cessation of all symptoms—as happened in Case 10. In our paper we confessed to the difficulty of placing these cases on one pathological basis, and admitted that it was possible that more than one morbid process was concerned. Dr. Beatty regards "spasm" as a more likely explanation of Case 10, and of some of the other cases. The same happy thought occurred to us when we wrote "the possibility of an element of spasm in several cases is suggested by the variability of the symptoms" (p. 360), although we regarded the spasm as a secondary element.

I am sorry that Dr. Beatty should have gathered that we had formed the opinion that non-organic obstruction of the oesophagus could not occur in infancy; our last remark before the summary of our paper was that "spasmodic contraction of the cardiac sphincter does occasionally occur in infants" (p. 364).

With regard to the diagnosis of congenital stenosis of the oesophagus, I am in complete agreement with Dr. Beatty about the value to be placed upon a skilful oesophagoscopy, and this is clearly stated in our article (p. 361). His alternative method of reaching the diagnosis by waiting to see what turns up at the post-mortem examination is of such doubtful value to the child that I cannot regret we failed to mention it.—I am, etc.,

London, W.1, March 11th. WILFRID SHELDON.

EFFECTS OF PROLONGED ADMINISTRATION OF LIQUID PARAFFIN.

SIR,—I am much interested in the note by "P. C. F." (March 8th, p. 478) with regard to liquid paraffin. I have many times noticed that the prolonged administration of liquid paraffin results in lack of growth, and even loss of weight, without the slightest tendency to improve the constipation. The following case illustrates the effect on the adult.

I was consulted during a ten months' voyage by an officer of the ship, who complained of loss of weight and of being thin. On inquiry, I found that he had been taking liquid paraffin for about four years for the treatment of constipation. He had become a slave to the drug, but his constipation was becoming more and more stubborn. He was of exceedingly spare build, and was becoming thinner. His appetite was very good, and he used to eat twice as much as anyone else. The urine was consistently normal. With the greatest difficulty I persuaded him to give up the paraffin and take some other aperient, such as phenolphthalein. After a week or so his appetite became less voracious, and he began to gain weight, and at the end of the voyage, four months later, had regained much of his former build.

I came to the conclusion that the patient had been the subject of self-starvation, due to the effect, as your correspondent suggests, of a film of oil always coating the mucous coat of the small intestine, thus preventing the proper assimilation of food. In this country millions of gallons of liquid paraffin are prescribed every year, and one wonders how far this fashionable aperient has been responsible for effects as described above.—I am, etc.,

Sedbergh, March 8th. THOMAS W. ROTHWELL, M.B. Ch.B.

SIR,—The use of liquid paraffin as a therapeutic agent is widespread, and it is generally believed that its action is purely mechanical and that none of it is absorbed. It is interesting, therefore, to note that Channon and Collinson[1] have found that, when the substance is administered to rats or to pigs, a certain quantity of it can be shown to accumulate in the liver. The proportion thus absorbed is small, but that any suffers this fate is contrary to the general belief. The authors also produce evidence that ordinary liquid paraffin is a mixture, not of purely aliphatic compounds, but of naphthenes (polycyclic compounds).—I am, etc.,

March 17th. E. H.

"A REACTIONARY DOCUMENT."

SIR,—The medical profession, as is perhaps natural, seems to be much less aware than the legal profession that the Local Government Act of 1929 left the Minister of Health an altogether inordinate degree of power, and the protest in your leader of March 8th (p. 453) indicates that the Minister has not been dilatory in using that power. It is unfortunate that the general public takes less and less notice of the proceedings in Parliament, for the natural consequence is that legislation is pressed through Parliament without incurring the useful check of public opinion.

There is less excuse for the belated discovery of the autocracy conferred upon the Minister by that Act, in that a statement was categorically made, during the debate on the bill in the House of Lords, by Lord Onslow, who was in charge of it for the Government, that "the power which the Minister would have is a greater power than ever was given to a Minister before," and the Lord Chief Justice, in his book *The New Despotism*, has made a very detailed and clear analysis of the position resulting from the Act, which he cites as one of the most glaring modern instances

[1] *Biochem. Journ.*, xxiii, p. 675.

of "administrative lawlessness." Power given to a department to make Orders modifying the provisions of an Act of Parliament really ultimately nullifies the authority of Parliament, as Lord Hewart points out, and various efforts were made during the passage of the bill to restrict this power. These efforts were unavailing; that power remains intact, and is now being exercised by the Minister. Lord Hewart closes his analysis with the following very pertinent observation:

"It may be observed that the *Times*, in a leading article in its issue dated February 16th, 1923, said, with reference to this clause enabling the Minister by Order to modify the provisions of the statute: 'The true precedents, it has been pointed out, must be sought further back than 1888. They are the pretensions to the dispensing powers under the Stuarts and the Statute—obsequiously passed by both Houses—which declared that anything enacted by King Henry VIII or Order in Council should have the force of law.'"

It is perhaps a little inconsistent for the medical profession, and for the *British Medical Journal* in particular, which has for so long acquiesced in the autocratic departmental control exercised under the Insurance Acts, to protest against a further extension of departmental control now promised by the Local Government Act, to the passage of which, with the menacing clause (Section 130), no organized opposition by the medical profession was made. As we sow, so shall we reap.—I am, etc.,

E. GRAHAM LITTLE.

House of Commons, March 11th.

*** The Order in question is not made under Section 130 of the Local Government Act, 1929, or under that Act at all. It is made under the Poor Law Act. Though the section named by Dr. Graham Little has nothing to do with this matter, its existence is not a belated discovery of the British Medical Association. The section was noted immediately on the introduction of the bill, and so far from efforts to restrict the power of the Minister under it being unavailing, the Association was not without influence in securing its substantial modification. However undesirable it may be to give to a Minister power to modify any Act of Parliament, there is no doubt that the issue of Regulations under many such Acts, and in accordance with their provisions, is an administrative necessity. The objection in the instance under discussion is not to the making of an Order, but to the character and terms of the Order actually proposed to be made. Though the Regulations contained in it purport to be merely a consolidation of Orders already in force, they will, in fact, re-emphasize and give a new sanction to methods of Poor Law administration, some of which are happily already obsolete or obsolescent, and obscure the opportunities for reform which should be open to the Poor Law Authorities from April 1st next.

ANAESTHETICS IN MIDWIFERY.

SIR,—As it is my appeal to which Dr. F. M. Rowland refers in your issue of March 1st (p. 414) I hope you will allow me the opportunity of a reply.

The whole of Dr. Rowland's letter seeks to perpetuate the fallacy that an anaesthetic is already given in every case when it is necessary. But the words "when necessary" reveal the weakness of his case. Extensive inquiries in maternity hospitals and other institutions have convinced me that all too often "when necessary" is almost synonymous with the need for a surgical operation. Long before this position is reached, the patient has undergone a degree of suffering which would not be tolerated for one instant in connexion with any operation not associated with childbirth. Most hospitals and institutions are ready and anxious to give an anaesthetic in every case in order to avoid shock; but the burden of their expenses is too heavy to permit the engagement of a resident anaesthetist. Since my fund has been started three London maternity hospitals have made applications for grants so that they may be enabled to give relief from suffering to still more patients than they do at present. If an anaesthetic is already administered in every case where it is necessary, why should these hospitals be so eager to secure the services of additional anaesthetists?

Dr. Rowland's statements would be more closely "in accordance with fact or practice" if every woman was, or could be, attended by a doctor at the birth of her child. A very large proportion of poor women are attended by midwives, who cannot administer an anaesthetic, and who summon a doctor only when complications arise to make his aid necessary. Does Dr. Rowland really believe that a midwife in ordinary practice in town or country can have a skilled anaesthetist at her call at a moment's notice under the provisions of the Midwives Act? No attempt is made—except in what is understood by Dr. Rowland as "when necessary" cases—to use anaesthetics generally, and until the social conscience is awakened to the need of developing our maternity services vast numbers of poor women must continue to suffer, whilst their wealthier sisters are enabled to purchase alleviation. It is to do away with this inequality that the appeal has been issued.—I am, etc.,

LUCY BALDWIN.

London, W.1, March 14th.

MARGARET MACDOWALL.

SIR,—Many of us feel that the death of Miss Margaret Macdowall must not pass without some reference being made to the valuable work that she has done. She was one of the pioneer workers in the care of mentally defective children in this country. Her intuitive understanding of their needs was remarkable. Her success did not lie in any formulated system, but rather in finding out the special requirements of each child so that it might be helped to get the best out of its limited mental capacity. Great insight, infinite patience, and an untiring devotion were the qualities which gave her work its intensely human value. In addition to her sympathetic care and training of these defective children, she had the gift of inspiring others and of imparting her outlook, and thus the unobtrusive work that she carried on for many years at Ealing, and later at Burgess Hill, has led to others following in her footsteps and developing her methods.—I am, etc.,

MAURICE CRAIG.

London, N.W.1, March 15th.

H. O. THOMAS'S LITERARY STYLE.

SIR,—In your editorial on Hugh Owen Thomas (March 1st, p. 406) you state that "he had not an attractive literary style." On reading this I went straight to my bookcase, took out the nearest of Thomas's books, opened it haphazard, and read the following:[1]

"Mr. Whiteside, now residing at the corner of Hawthorne-road and Benedict-street, while engaged in a bakery, dislocated his shoulder. He went immediately after the accident to a public hospital, where, while he was under an anaesthetic, the house surgeon attempted to reduce the displacement but failed. On the following day he repeated his visit, and was under the influence of an anaesthetic for six hours, while several of the honorary staff surgeons were superintending and assisting at attempts at reduction, but with no success. After this the patient remained contented for six weeks, when he decided to seek for aid from a popular practitioner in Manchester, but on his way to the railway station he altered his intention and came and consulted me. Stipulating that he should first procure me a photograph of the part, I promised that an attempt at reduction would be made by me, which was fulfilled next day. The dislocation was reduced in twenty minutes."

If this is not attractive, what is?—I am, etc.,

PAUL BERNARD ROTH.

London, W.1, March 5th.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 14th the following medical degrees were conferred:

M.B., B.CHIR.—*R. M. Windeyer, T. N. Parish.

* By proxy.

UNIVERSITY OF LONDON.

REGULATIONS for the academic diploma in clinical pathology have been approved and can be obtained on application to the Academic Registrar.

The Chancellor has reappointed Professor Rushton Parker to be his representative on the Court of Governors of the University of Liverpool for a further period of three years. Professor William Wright and Mr. W. G. Spencer have been appointed governors of East London College and Westminster Hospital Medical School respectively. Mr. G. J. Jenkins has been appointed an external examiner in oto-rhino-laryngology for 1930.

An interim grant of £75 has been made out of the Thomas Smythe Hughes Medical Research Fund to Kathleen Edith

Chevassut for the continuation of her research on the etiology and treatment of disseminated sclerosis, which is being carried out at Westminster Hospital.

Applications for grants from the Thomas Smythe Hughes and Beaverbrook Medical Research Funds must be sent in between May 1st and June 15th, 1930, accompanied by the names and addresses of not more than two persons to whom reference may be made. The grants are allocated annually for the purpose of assisting original medical research. Full particulars may be obtained on application to the Academic Registrar.

UNIVERSITY OF LIVERPOOL.

At a congregation to be held on June 5th the honorary degree of D.Sc. will be conferred on Dr. George Barger, F.R.S., Professor of Chemistry in relation to Medicine in the University of Edinburgh.

UNIVERSITY OF EDINBURGH.

Among the honorary degrees which the University proposes to confer are the LL.D. on Sir Thomas Barlow, Bt., Physician-Extraordinary to the King and consulting physician to University College Hospital; Sir David Wallace, F.R.C.S.Ed., consulting surgeon to the Royal Infirmary, Edinburgh; Dr. K. F. Wenckebach, F.R.C.P., Emeritus Professor of Clinical Medicine in the University of Vienna; and Sir William B. Hardy, F.R.S., Director of Food Investigation, Department of Scientific and Industrial Research.

NATIONAL UNIVERSITY OF IRELAND.

The Senate met on March 13th.

A resolution of condolence was adopted on the death of Dr. Maurice R. J. Hayes, Professor of Materia Medica and Therapeutics in University College, Dublin.

The Senate, having considered the reports of the examiners upon the published works submitted to them, decided that the degree of M.D. should be conferred on E. J. Keenan and S. A. McSwiney.

The following appointments were made: Professor Thomas Walsh was appointed to represent the University at the sixteenth annual conference of the National Association for the Prevention of Tuberculosis, to be held in London in July, and Dr. Denis J. Coffey was appointed to represent the University at the jubilee celebrations of the University of Manchester in May.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council meeting of the Royal College of Surgeons was held on March 13th, when the President, Lord Moynihan, was in the chair.

The congratulations of the Council were given to Lord Moynihan on the presentation to him by H.M. King Fuad of the Grand Cordon of the Order of the Nile.

Professor G. Elliot Smith attended and was presented by the President with the honorary Gold Medal of the College, with a document declaratory of its award, in appreciation of his services to the Museum, more especially in preparing a descriptive catalogue of the vertebrate brains and in securing for the College the valuable Nubian collection of pathological specimens from Egypt.

Licences in Dental Surgery were granted to 34 candidates.

Diplomas in Ophthalmic Medicine and Surgery were granted, jointly with the Royal College of Physicians, to 16 candidates.

Mr. Fagge was appointed as representative to serve upon a subcommittee of the People's League of Health to consider the subject of "The cause and eradication of bovine tuberculosis" and the desirability of holding an international conference thereon.

The Services.

HONORARY SURGEON TO THE KING.

Group Captain Henry Cooper, principal medical officer for the Air Defences of Great Britain, has been appointed an Honorary Surgeon to the King, in succession to Air Vice-Marshal David Munro, C.B., C.I.E.

ROYAL NAVY MEDICAL CLUB.

The annual dinner of the Royal Navy Medical Club will take place at the Trocadero Restaurant, Piccadilly Circus, on Thursday, April 24th, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the honorary secretary, Royal Navy Medical Club, Queen Anne's Chambers, Tothill Street, S.W.1, not later than seven clear days before that date.

DEATHS IN THE SERVICES.

Lieut.-Colonel Hugh Latimer Donovan, R.A.M.C. (ret.), died at South Yardley, Birmingham, on February 28th, aged 74. He was born on July 30th, 1855, was educated at Queen's College, Cork, and graduated as M.D. and M.Ch. in the Royal University of Ireland in 1877. Entering the army as surgeon on February 3rd, 1878, he became surgeon lieutenant-colonel after twenty years' service, and retired on February 23rd, 1898. He was employed for some time after his retirement at Warwick. He served in the Egyptian war of 1882, receiving the medal and the Khedive's bronze star; and in the Sudan campaign of 1885, when he was present at the action of Tofrek, was mentioned in dispatches in the *London Gazette* of August 25th, 1885, and gained two clasps to his medal. He rejoined for service in the war of 1914-18, when he served for some time in the Western Command.

Obituary.

H. W. ARMIT, M.R.C.S., L.R.C.P.,

Editor, Medical Journal of Australia.

Members of the British Medical Association in this country who knew Dr. Armit before he went to Sydney seventeen years ago to become Editor of the *Medical Journal of Australia* will regret to hear of his death, on March 12th, after a brief illness.

Henry William Armit, younger son of William Armit, sometime secretary of the Hudson's Bay Company, was born in 1871, and studied medicine at St. Bartholomew's Hospital, obtaining the M.R.C.S., L.R.C.P. diploma in 1894. With a good working knowledge of several modern languages he combined an interest in scientific research, and, in the intervals of practice in the North-West of London, he found time to translate Ehrlich and Lazarus's *Anaemia* and von Schrötter's *Hygiene of the Lung in Health and Disease*. He also attended a number of medical congresses on the Continent, and supplied reports of their proceedings to the *British Medical Journal*. In this capacity he visited Paris, Berlin, Lisbon, and Budapest. Between 1904 and his departure from England Dr. Armit held a number of local offices in the British Medical Association and took an active part in professional politics. For five years he represented the Hampstead Division in the Representative Body, and became chairman of that Division in 1910, having previously acted as assistant honorary secretary and vice-chairman. He was a member of the Metropolitan Counties Branch Council from 1907 to 1911, and vice-president of the Branch in 1909, and he had served on more than one central committee.

In 1913 a decision of great importance was taken by the Federal Committee of the Australian Branches of the British Medical Association. At that time two medical journals were already in existence in the Commonwealth, each with vested interests. It was decided to form a company with limited liability to acquire the interests of these two periodicals, and to found a weekly journal for the whole of Australia, to be called the *Medical Journal of Australia*, incorporating the *Australasian Medical Gazette* and the *Australian Medical Journal*. In accordance with this decision Dr. Armit was invited to become whole-time Editor, with offices in Sydney, and the first issue of the new periodical appeared under his direction on July 4th, 1914. Armit shouldered this heavy task in unaccustomed surroundings with characteristic energy and resource. He was a man of great industry and pertinacity, and the *Medical Journal of Australia* made steady progress. Many difficulties which presented themselves, both during the war and after, were gradually overcome, and in this the constant help of Dr. R. H. Todd was invaluable.

In his editorial work Armit was most painstaking, and he acquired at first hand a thorough knowledge of all the technical details of the printing office and the publishing department. His acquaintance with foreign medical literature, and his belief in the importance of keeping the Australian profession abreast of new work in other countries, found practical expression in his pages, and more particularly in the summaries of articles in contemporary journals, which almost from the beginning have been a feature of the *Medical Journal of Australia*.

J. W. L. SPENCE, L.R.C.P.and S.Ed., L.R.F.P.S.,

Medical Officer in Charge of the Electrical Department, Royal Hospital for Sick Children, Edinburgh.

The death took place on March 15th, at his residence at Palmerston Place, Edinburgh, of Dr. J. W. L. Spence, at the age of 58. Well known as a radiologist in that city, and as one of the pioneers of radiology in the Edinburgh Medical School, he had for many years been suffering from the effects produced by *x* rays at an early stage of his employment of this diagnostic means, and for some months his state of health had been very serious.

John Webster Lowson Spence was born at Smyrna in 1871, the son of a well-known missionary, and lived afterwards at Constantinople. After studying medicine at Edinburgh, he took the Triple Qualification in 1893, and

thereafter held a resident post in the Deaconess Hospital, Edinburgh. While conducting a general practice on the north side of the city he began to devote himself to what was then a new subject—medical electricity and radiology; he had been associated with Wilhelm Röntgen since 1897. The electrical department had been established in the Royal Infirmary of Edinburgh in 1896 under the late Dr. R. Milne Murray; he was succeeded in 1901 by Dr. Dawson Turner, who had already taken up the newly introduced diagnostic means of the *x* rays. Dr. Spence almost at once became his clinical assistant, and in 1907 he was placed in charge of the electrical and radiological department of the Royal Edinburgh Hospital for Sick Children. This post he retained for a period of twenty-two years, until his resignation at the end of last year. He also acted for many years as radiologist to Leith Hospital and to the Church of Scotland Deaconess Hospital, as well as, for a shorter period, to the Craigleith War Pensions Hospital. During the early days of the use of *x* rays, when Dr. Spence rendered most valuable service as a pioneer, the necessity of protection was little understood; at this time he suffered from *x*-ray dermatitis, which progressed seriously in later years. About 1908 his hands began to suffer severely, and in 1910 it was necessary to remove a finger of the right hand. The spreading destruction and ulceration involved a series of operations, till, in 1916, it became necessary to amputate his right arm near the shoulder. Despite this disability, he continued full work as a radiologist, to which he had now entirely devoted himself both in hospital and in private practice. In the last five years the left hand had also suffered serious damage, and his general health was greatly deteriorated, so that for some months past he had been confined to bed; it recently became necessary to remove the greater part of the remaining hand. For his services in *x*-ray work Dr. Spence was, in 1922, awarded a bronze medal and an annuity by the Carnegie Hero Fund Trustees.

Dr. Spence made numerous contributions to the literature of his specialty, including "A review of medical electricity" contributed to the *Edinburgh Medical Journal* in 1903, "*X* rays in the treatment of pyorrhœa alveolaris" in the *Montreal Medical Journal* of the same year, and "A unique case of congenital scoliosis" published in the *Archives of Pediatrics* in 1913. He was peculiarly skilful in the management of patients who were sometimes nervous in the unusual surroundings of a radiological examination, and this applied particularly to his work among children, with whom he was a universal favourite. His brightness and cheerfulness made him a welcome entertainer at the Christmas celebrations of the Sick Children's Hospital and Deaconess Hospital, in which he regularly took part. His courageous personality, as well as his radiological skill, will be greatly missed in Edinburgh medical circles.

The death of Dr. SIMSON CARSTAIRS FOWLER of Juniper Green, Midlothian, on February 8th, brought sorrow to a wide circle of friends. He had undergone an operation in the spring of 1929, but had quite recovered from it, and was in excellent health until two days before the end. He was born in Calcutta on December 26th, 1857. His father was a sea captain—both he and his wife came originally from Fife—and often took his family with him on his voyages. They stayed in Calcutta till 1863, when they returned to the family home in Scotland. After schooldays in Edinburgh Simson Fowler was with the Scottish Union and National Insurance Company, where he did well. But his heart was not in that type of work and he insisted on going into medicine at the University, where he graduated in 1887. After study in Berlin and Vienna, he went as assistant to the late Dr. Wallace in Cardiff for two years, but longed for Scotland. He was for a short time with the late Dr. Dow in Dunfermline, but when the practice of the late Dr. Gordon in Juniper Green became vacant he bought it in 1890, and had lived there ever since. Professor Lovell Gulland writes: "Happy is the nation that has no history," and happy is the doctor who spends all his working life among his own people, becoming year by year more indispensable to them and more beloved by them, who sees "his babies" growing up, marrying, and founding families of their own, who becomes an institution of the place, as weel kent as the kirk, trusted and honoured by everyone. In such a life there are few outward events to chronicle. It is a quiet influence for good which sweetens the life of the whole community and furnishes a priceless example of duty done quietly and ungrudgingly. We recognize gratefully that there are many doctors of this type in Scotland, but Fowler was an outstanding example. Not only had he charge of a large practice, which in later years he shared with Dr. Sellar, but he was medical officer of Colinton parish, and doctor to many of the charitable institutions in the neighbourhood. During the war he was in charge of the Red Cross Hospital at Kingsknowe, and he was for some time chairman of the Panel Committee of Midlothian, and was greatly interested in that and every other form of medical public work. He was a first-rate doctor, kept himself well abreast of all new things, and had the faculty of discerning what was good in the new. As happy in attending a poor widow for nothing as in the homes of the well-to-do, he was equally trusted and welcomed by all classes.

We record with regret the death, on March 1st, at the age of 54, of Dr. J. DONALDSON, who for the last thirty years has been well known in Middlesbrough. James Donaldson, who was born in Lanarkshire, received his medical education at Edinburgh, where he graduated M.B., Ch.B. in 1898. After holding the post of assistant surgeon to the Northampton General Infirmary he was for three years house-surgeon at the North Riding Infirmary, and then commenced general practice in Middlesbrough. Soon afterwards he was appointed surgeon to the North Riding Infirmary, and became honorary consulting surgeon to that institution a year or two ago. He was chairman of the Cleveland Division of the British Medical Association from 1922 to 1923. During the war he held a commission in the R.A.M.C., and served in France and Italy. A colleague writes: By the death of James Donaldson the Cleveland Division, and, in particular, the medical profession in Middlesbrough, loses one of its stalwarts. Donaldson was a keen B.M.A. man. He became a member soon after graduating, and he served his Division with faithfulness and zeal. It was not long before he was secretary, and his appointment as chairman was only delayed on account of his war service. He was a member of the Executive Committee of the Division and of the Council of the North of England Branch for many years. In addition, he was the first secretary of the Middlesbrough Panel Committee, afterwards becoming its chairman. He also served on the Executive Committee of the Middlesbrough Public Medical Service from its inception in 1912, and was chairman of this organization for two years. His colleagues will miss him sorely. Donaldson was an enthusiastic Freemason. He was a Past Master of the Ferrum Lodge and P.Z. of the Ferrum Royal Arch Chapter. He had received high provincial Masonic honours, of which he was very proud. The North Riding Infirmary benefited for a long period of years from his zealous and untiring services. He loved his hospital, and gave to it ungrudgingly of his best as honorary surgeon. Donaldson's death will be greatly deplored by a large circle of friends in all walks of life.

Dr. GEORGE MURPHY, who died on February 26th, at the age of 80, was the oldest member of the medical profession in Carlisle. He went to the Cumberland Infirmary as a pupil in 1868, being primarily concerned with the out-patients, though on occasion he was left in sole charge of the hospital. He completed his student career at Queen's College, Birmingham, and obtained the diploma M.R.C.S.Eng. in 1873, and the L.R.C.P.Ed. in the following year. After a short period of practice at Wednesbury he returned to Carlisle, where he built up an extensive connexion, taking particular interest in midwifery cases. For many years he was medical officer for the Stanwix district of the Carlisle Union, and public vaccination officer. He was also medical officer to the Carlisle Foresters and the lodge of Oddfellows. Dr. Murphy was a member of the British Medical Association, and served on the local general committee when the Annual Meeting was held at Carlisle in 1896. During the war he acted as anaesthetist at various war hospitals in the district.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

IN the House of Commons this week the Navy Estimates were introduced and discussed. References were made to the shortage of medical officers. Progress was made with the Coal Mines Bill in committee. The Mental Treatment Bill, Road Traffic Bill, and Canals Bill were before standing committees. The last has been considerably amended.

On March 18th the Conservative Parliamentary Agricultural Committee decided to press the Minister of Health to withdraw the Order prohibiting the exhibition of cattle yielding "certified" and "Grade A" (T.T.) milk.

The report of the departmental committee on the Poisons and Pharmacy Acts was presented to the House and published. This incorporates a draft bill, but the Home Office does not expect to introduce legislation on the subject in the current session.

Dr. Fremantle gave notice of his intention to ask the Minister of Health, on March 20th, if he would introduce a short indemnifying bill to exempt present sitting medical members of county and county borough councils from their disabilities to act as from April 1st next during the remainder of their present period of office, pending the reconsideration or reorganization of the methods of payment to medical practitioners for minor medical services rendered on behalf of local authorities in the course of their private practice. Dr. Fremantle further wished to ask the Minister of Health if he was aware that in rural parts of the country generally, and particularly in such rural counties as the county of Huntingdon, all practising medical practitioners were rendered ineligible for service as members of county councils by the provisions of the Local Government Act, 1929, and that therefore such councils as desire to have medical members, whether co-opted or elected, for their public health, maternity and child welfare, and midwives Acts, mental deficiency, and other committees were unable to obtain them.

The Reservoirs (Safety Provisions Bills) and the Performing Animals (Regulation Amendment Bill) were read a second time by the House of Lords on March 13th. On March 14th a Protection of Animals Bill, introduced by Mr. Foot, was read a second time in the House of Commons. Its purpose is restricted to the prohibition of rabbit coursing and the hunting of the carted stag. An Unlawful User of Vehicles Bill, to provide penalties for the unauthorized use of motor cars without intention to steal, was ruled out of order, on March 14th, by the Speaker, on the ground that the subject is already covered by a clause in the Road Traffic Bill.

Mental Treatment Bill.

COMMITTEE STAGE CONTINUED.

Discussion of Clause 5 of the Mental Treatment Bill was resumed by a Standing Committee of the House of Commons on March 13th. Mr. GREENWOOD resisted an amendment moved by Sir Basil Peto, that persons received for temporary treatment but unable to express a desire for it might be received in institutions approved by the Minister of Health and not containing certified patients. Mr. Greenwood said the Royal Commission had reported strongly against putting this matter into the hands of the Minister instead of into those of the Board of Control. It could not be done without overhauling the whole of the lunacy laws.

The amendment was negatived. So was an amendment in which Mr. Kinley proposed that any application for the treatment of a person under Clause 5 must state in distinctive type that the patient may, on the report of a Commissioner, be certified and removed to a lunatic asylum.

Mr. Greenwood accepted an amendment, moved by Dr. Fremantle, that application for the treatment of patients incapable of expressing their desires should be made to the person in charge. Answering arguments from Dr. Morris-Jones, Mr. GREENWOOD moved to add at the end of the subsection dealing with applications the words:

"Provided that in the case of a person who is to be received into a licensed house or a nursing home, or into charge as a single patient, the recommendation shall not be signed by the person in charge, or by any person in the employment of the person in charge, or by any person interested in the house or home, or by any person in the employment of any person so interested."

He said that in public institutions the doctor could have no pecuniary interest, and the point did not arise.

On the motion of Sir BOYD MERRIMAN, the committee made an amendment providing that each of the medical practitioners making a recommendation under Clause 5 should state the grounds on which he based his recommendation.

By 18 votes to 10 the committee defeated an amendment by Mr. RICHARD RUSSELL, which proposed that the Board of Control should, on the signed request of the patient, furnish to him or his authorized representative free of cost a copy of the application on which he was received and of the recommendation accompanying the application.

Drafting and consequential amendments were made to the subsections which followed.

Mr. KINLEY moved to omit Subsection (14), which empowers the Board to order the release of a person detained under Clause 5, or alternatively his treatment under the Lunacy Act as a person of unsound mind. The amendment was negatived. On the motion of Mr. GREENWOOD the committee added at the end of the clause the proviso:

Any approval granted by the Board of Control under this section may be granted subject to such conditions as the Board think proper and may be revoked at any time.

On the motion that Clause 5 stand part of the bill, Dr. FREMANTLE said he had been urged that the detention of these patients should be allowed for two years. In the experimental state of the measures he was content with the section as it stood. As the public acquired confidence in its working there would be a movement to extend the period.

The committee agreed that the clause stand part.

In moving that the committee adjourn, Mr. GREENWOOD said: "I would remind the committee—I am not making special complaints—that this is our sixth meeting, that we have only dealt with five clauses, and there are over twenty clauses in the bill and the schedules. It is very necessary that I should get the committee stage finished at a pretty early date."

Dr. FREMANTLE could not admit that the bill was an agreed one; it required thorough consideration; there was much disagreement about Clauses 6, 7, 11, and 16.

The committee then adjourned.

The Mental Treatment Bill was again considered by the Standing Committee on March 18th. Mr. GREENWOOD moved an amendment to Clause 6 giving power to local authorities, subject to the approval of the Board of Control, to contract for the reception and treatment of temporary patients in any registered hospital, institution, hospital, or nursing home approved by the Board of Control. The amendment was accepted. Mr. Greenwood moved a series of amendments framed after consultation with the County Councils Association with a view to relieving the authorities from the obligation of securing the approval of the Board of Control for administrative schemes. Approval was still to be required for research.

Dr. FREMANTLE said that personally he was not altogether pleased at the removal of the necessity for the Board of Control's approval. Dr. MORRIS-JONES associated himself with Dr. Fremantle.

Mr. GREENWOOD, in reply to questions, made it clear that the approval of the Board of Control was only removed in respect of the questions dealt with in Subsection (3). The approval of buildings remained as at present. The amendments were agreed to.

Clause 6 as amended was added to the bill, and the committee adjourned.

Road Traffic Bill.

On March 11th the Standing Committee on the Road Traffic Bill considered Clause 5 (provisions as to physical fitness of applicants for licences).

Dr. SALTER moved that the applicant should "produce a certificate in the prescribed form showing that he has satisfactorily passed an eyesight test as to visibility and colour." He said he understood the Ministry of Transport intended that when the bill became law every applicant for a licence should make a declaration whether he was suffering from certain physical disabilities. The Ministry of Health had drawn out a form with a long list of specified disabilities. Dr. Salter contended that such a declaration was useless in regard to eyesight. Large numbers of persons suffering from grave visual defects were unaware of these, and could honestly make a declaration that they were capable of driving. Ophthalmic surgeons told him that they had been consulted by people with grave eye trouble, whose first intimation that they had a visual defect was that they met with an accident while driving a car. Dr. Salter contended that four classes of persons should not be permitted to drive on the roads at all. These were people with extreme myopia, people suffering from night-blindness (who were certainly not less than 5 per cent. of the population), people suffering from disease of the eye and central nervous system, whose field of vision was irregular in shape with large blind spots, and the many thousands of people who were totally colour-blind. An authoritative work on diseases of the eye asserted that 3.5 per cent. of men and about 1 per cent. of women were congenitally colour-blind. These persons could not discriminate between the automatic colour signals which the Minister of Transport was encouraging great towns to establish. These were red for "stop," green for "go on," and amber for "about to release." People had already been charged with overrunning the colour signals in Derby and other Northern towns, who pleaded that they were colour-blind. On the railways it had been found that though a man might pass

a colour test, five years later his colour vision might be defective. Therefore it was essential that every time a man applied for a motorist's licence he should submit a medical certificate to the effect that he was not colour-blind. Within the last twelve months in Prussia a compulsory test for colour-blindness had been enforced.

Lord ERSKINE submitted that the words proposed by Dr. Salter were redundant, but added that he understood the disease of colour-blindness was increasing.

Mr. HERBERT MORRISON (Minister of Transport) said Clause 5 laid it down that certain diseases or disabilities would be an absolute bar without appeal to the driving of a motor vehicle. He did not wish to make these bars numerous. In a whole field of diseases or disabilities there was an element of doubt, and the driver should have an opportunity to claim a test. He would regard sight which if corrected by spectacles was still extremely short as an absolute bar to the grant of a driving licence. He could not say whether the limit would be 25 or 50 per cent. of the normal vision, but a standard would be laid down in the form and it would be for the applicant to satisfy himself that his sight reached that standard. It was not proposed that the applicant should produce any form of medical certificate; with great respect to the profession, there would not be complete reliance that medical certificates were always given in strict accordance with the facts, when perhaps a man's employment might depend on the result of this certificate. Nor did he propose the alternative method of maintaining doctors in the public service who would be employed upon these tests. He relied upon the fact that a man who made a false declaration was liable to very severe penalties. In regard to light signals and colour-blindness, a man who was colour-blind could in the daytime see the position of the light and know whether it was the first, second, or third light. The same man would also be able normally to read the word "stop," "go," or "caution." This was not a completely satisfactory assurance, but it was sufficient to warrant the committee in not imposing conditions which would be resented by the trade unions, who were apprehensive about all forms of tests. It might be that Parliament would pass further legislation in the future.

Mr. GEORGE OLIVER said that he was colour-blind, and before coming to the House of Commons was employed by a motor firm. He had driven constantly on the roads. He contended that it was possible for a colour-blind man to notice the change of a road sign from green to red or vice versa, and said that during a long experience on the road he never met with a serious accident.

The amendment was then defeated by 44 votes to 4.

Other amendments designed to ensure that the applicant for a licence should pass a driving test, and alternatively that he should not be disqualified for a disease or physical disability except those to be specified in a schedule issued by the Minister, were all rejected, and Clause 5 was added to the bill with drafting amendments.

Mr. MORRISON announced incidentally that he was in negotiation with ex-service men's organizations concerning the licensing as drivers of men who had lost a leg.

The committee adjourned until March 13th, when further clauses were considered.

The Navy Estimates.

On March 17th the House of Commons considered the Navy Estimates. Mr. ALEXANDER, First Lord of the Admiralty, in moving that the House should go into committee, said the Medical Director-General reported that the health of the fleet personnel for the past twelve months had been very good and no serious epidemics had occurred. Some concern was felt, however, over the difficulty of obtaining an adequate supply of medical officers, in spite of special efforts during the year by the Medical Director-General, and he appealed to medical members of the House to assist in this effort. The provision now made for the welfare of the men was a great factor in maintaining general health and efficiency.

On the vote for personnel, in Committee of Supply, Major Ross said that it appeared that nearly all the stores were being reduced—victualling, clothing, and even medical. The sum provided by the First Lord for the medical stores and surgical appliances had been reduced by some £11,000, and he suggested that Mr. Alexander was not keeping the stocks which had been supplied up to the standard.

Dr. VERNON DAVIES said that the First Lord of the Admiralty, in his original statement to the House, was rather perturbed at the lack of medical men. He was reducing the personnel of the Navy by 2,750, and he had said that he could not understand why the medical services, not only of the Navy, but of the Army, were not more popular. He (Dr. Davies) suggested that probably the terms were not quite good enough, and yet the terms were very good. The First Lord had visualized a time when boys from elementary and secondary schools would pass through the university and into the services of the Crown. They were doing that now in the medical profession, and that was the difficulty that they were up against. If he might say so without offence, medicine was becoming more of a trade and less of a profession. Many of these young men had no money; they had spent all their money on their education. They had become qualified, and were out to do the best they could for themselves. They had several opportunities before them in civil life. A young doctor could set up in a national health insurance panel practice, and there were other openings, but if he went into the Navy, even on the short service system, even though he could go out with a gratuity of £1,000, he had to give three years or five years of his time. He had to go abroad. He dare not get married, because the Admiralty would not give him a pension. On the other hand, those who did not go into the service but stayed at home, could earn as much money; they could get married and have home life. They had before them specialized services, such as tuberculosis service, school medical services, and others, in which they could work for six or seven hours a day on five days of the week, and earn from £600 to £900 a year. With that prospect on shore, why should a young doctor go to sea? He would be very silly to do so unless he had a great love of the sea. The First Lord might make up his mind that the medical services of the Crown would have to be amalgamated. It was no use asking the heads of the separate medical services to agree to such a proposal, because they were not going to commit hara-kiri. The Government would have to make up its mind that when it wanted medical men it was in competition with the great civil medical services of the country, both national and municipal. His suggestion, for what it was worth, was: Would it not be possible to give to men who had served in one or other of the services for five years a preferential claim on all medical appointments under the Crown or in the municipalities? It really was a question of choice between a man who had given five years of his life to the service of the country voluntarily and the man who had stayed at home. When the Government wanted a medical man for the Ministry of Health or any other department, the man who had served his country for five years should have a preferential claim. By offering an inducement like that they would get these young men into the service. Unless they had an efficient medical service they would not get a healthy Navy; if they did not get a healthy Navy they would have an inefficient Navy, and it was the medical men who won the war. There was never a war in all history where there was less sickness and disease, or where more people were cured after being disabled. It was the medical profession, absolutely, which won that war by keeping the men fit. It was no use having the ships unless the men were healthy and fit. He hoped that the First Lord would not be discouraged at the lack of flow into the medical service, but would recognize that there were more tempting offers made outside, and that it was up to his department to see if the service could not be made additionally attractive to these men.

The vote was agreed to.

Silicosis.

Mr. CLYNES, in reply to Mr. Kelly on March 12th, said the only complete figures he could give at present for cases of silicosis in 1929 were those dealt with under compensation schemes for silicosis in the refractories and sandstone industries. Under the refractories scheme there were 18 cases of partial disablement, 1 case of total disablement, and 10 fatal cases. Under the sandstone scheme, which came into force on April 1st, 1929, there were 2 cases of partial disablement, 7 cases of total disablement, and 5 fatal cases. The figures for the industries included under the other two schemes now in force were not yet available, but roughly, 103 cases in these industries, about half of which were fatal, had come to the notice of the department.

Mr. TURNER told Mr. Hopkin, on March 13th, that medical research was being instituted into the whole question of pulmonary disease from silica and other dusts, but he had no information pointing to an increase in the number of cases of silicosis in the anthracite district of South Wales, or any evidence of cases of disablement due to anthracosis.

Cost of Mental Hospitals.—Mr. GREENWOOD told Mr. Kinley, on March 13th, that the expenditure of local authorities in maintaining mental hospitals under the Lunacy Act for the year ended March 31st, 1929, amounted to £7,881,256, exclusive of loan charges. During the same period expenditure in respect of mental defectives borne by the local authorities was £607,301, and by the Exchequer £609,519. Local authorities had provided ninety-nine mental hospitals, fourteen registered hospitals were supported by voluntary contributions, and there were fifty-four institutions under private ownership. The Army and Navy each provided one institution, and there was one criminal asylum. The total number of patients under care amounted to 123,922.

Wells Mental Hospital.—Replying to Mr. Gould, on March 13th, Mr. GREENWOOD said the weekly number of hours worked by the nursing and domestic staff in Wells Mental Hospital was in accordance with the recommendations of the Joint Conciliation Committee of the Mental Hospitals Association and the National Asylum Workers Union—namely, sixty-six hours a week inclusive of meals. There were seventy-five beds in one dormitory of a size which gave 600 cubic feet of space for each occupant. That was unfortunately the best accommodation available at the moment. He would consider making representations through his department for an early change in the sleeping accommodation.

Residential Care of Mental Patients.—Miss LAWRENCE told Dr. Vernon Davies, on March 12th, that 29 out of 1,924 local authorities (or combinations of authorities) had made some provision for the residential care of the mentally defective. The present accommodation was inadequate, and, if the figures estimated by the Departmental Committee on Mental Deficiency were accepted, the shortage of beds was probably not less than 20,000.

Tuberculous Mental Patients.—Answering Dr. Vernon Davies on March 12th, Miss LAWRENCE said there was no organized liaison throughout the country between mental hospitals and tuberculosis officers of county or county boroughs, with a view to the diagnosis of tuberculosis among the patients in these hospitals. Many mental hospitals now received regular visits from consulting physicians and other specialists, and possessed special facilities for the diagnosis of pulmonary tuberculosis, including *x*-ray apparatus.

Lunacy Observation Wards.—Answering Mr. Arthur Richardson, on March 13th, Mr. GREENWOOD said that after the Poor Law guardians had been abolished, the use of lunacy observation wards would depend mainly on the decision of local authorities about the purposes for which the Poor Law infirmaries, of which these wards formed part, should then be used. He added that a provision in the Mental Treatment Bill would facilitate the use of such wards for mental patients.

Psittacosis.—In reply to Mr. Graham White, Mr. GREENWOOD said, on March 13th, that the results obtained concerning the discovery and isolation of the virus of psittacosis at a London hospital had not yet been confirmed, but a great deal of work was in progress, and he hoped for valuable results.

Silicosis.—Mr. CLYNES told Mr. Rennie Smith, on March 6th, that he hoped to present a bill dealing with silicosis before the end of March. The committee appointed by the Medical Research Council would advise on and supervise further investigation of pulmonary silicosis and other pulmonary conditions associated with inhalation of dusts from industrial processes, and in co-operation with the Factory Department, would obtain more accurate knowledge of causes and diagnosis.

Small-pox.—Mr. GREENWOOD told Mr. Freeman, on March 18th, that in 1929 the cases of small-pox notified in England and Wales numbered 10,967. Among those cases 39 deaths occurred which were classified as small-pox. These figures were provisional.

Treatment of Rheumatism.—Mr. GREENWOOD stated, on March 13th, in reply to Mr. Graham White, that until further experience had been gained of the treatment of rheumatism at the new clinic established by the British Red Cross Society and elsewhere, he considered it would be premature to appoint a committee to consider the best means of extending facilities for treatment. He was prepared to give sympathetic consideration to any practicable proposals which might be submitted by local authorities for provision of facilities for treatment. Dr. FREMANTLE suggested that more results would be produced by multiplying the Government grants to medical research. Mr. Greenwood did not reply.

Deaths due to Influenza.—Mr. GREENWOOD said, on March 13th, in reply to Dr. Morris-Jones, that no information was available with regard to the number of cases of influenza among the insured population, but from the Registrar-General's weekly returns it appeared that the number of deaths due to influenza registered in 107 great towns in England and Wales was 5,347 during the first eight weeks of 1929, as against 582 during the same period of 1930.

Experiments on Animals.—Mr. CLYNES, replying to Mr. Freeman on March 17th, said that the contents of certificates under Section 5, Cruelty to Animals Act, 1876, for experiments, were always and necessarily treated as confidential.

Radium.—In reply to Commander Kenworthy, on March 6th, Mr. GREENWOOD stated that the Radium Trust had thought it best, as a primary object, to obtain radium from existing sources, including such supply as was available in this country. Efforts to obtain an independent supply in the Empire and from Cornwall were under consideration. The price paid by the Radium Trust for radium would be made public in the annual report.

Reconstituted Milk and Artificial Cream.—Mr. GREENWOOD told Mr. Everard, on March 6th, that he was aware that at a recent food and cookery exhibition at Olympia reconstituted milk had been supplied to the public. He did not think it necessary to inform food and drug authorities that the sale of reconstituted milk was illegal. Mr. Greenwood further said, in answer to Colonel Ruggles-Brise, on March 6th, that he could not introduce legislation requiring all users of emulsifying machines to disclose the fact that they were supplying artificial cream. The Artificial Cream Act controlled the sale of artificial cream, and provided for the registration of premises where it was manufactured or sold.

Protection Against Gas Attack.—Mr. MACDONALD, on March 17th, in reply to a question, said that in view of the ratification, last year, of the Geneva Gas Protocol of 1925, by most of the important European States, including this country, and of the other international undertakings and agreements for the preservation of peace, the present time was not opportune to press on with plans for protecting the public against gas attack. Considerable preparatory work had been done by the Committee of Imperial Defence on this problem before ratification of the protocol. This work would always be available.

Clinics for Orthopaedic Cases.—Mr. GREENWOOD told Colonel Acland-Troyte, on February 27th, that under Section 14 (1) of the Local Government Act, 1929, county councils would be able to provide clinics for treatment of orthopaedic cases and to provide all necessary appliances. As a rule orthopaedic cases did not require special nourishment as part of treatment. Exceptional cases which did require it should receive treatment in hospital.

Proposed Medical Training School in Tanganyika Territory.—Replying to Mr. Ormsby-Gore on March 5th, Dr. SHIELS said the proposed medical training school in Tanganyika Territory was for further training of African dispensers and sanitary inspectors, and aimed at producing eventually a grade of African sub-assistant surgeons. Miss RATHBONE asked whether it was proposed to train women as medical officers and hospital assistants, in view of the grave scarcity of such trained women in the colony. Dr. SHIELS said he would take the suggestion into consideration.

Increase of Factory Inspecting Staff.—On March 10th Mr. CLYNES informed Mr. Kelly that no addition was made last year to the total strength of the factory inspecting staff. Changes which the Government had decided to make in the strength and organization of the inspectorate included increases, to be spread over five years, in the general inspection staff and the technical branches, which included the medical side. The medical staff would be raised from five to eight, and in the technical branches two medical inspectors would be added.

Medical Officers as Sanitary Inspectors.—Mr. JOHNSTON, replying to Mr. McKinlay, on March 4th, said that his attention had not been called to what that member described as a growing practice in Scotland of appointing medical officers as sanitary inspectors. He could not accept the suggestion that a medical practitioner who was also the holder of a diploma in public health was unqualified for the office of sanitary inspector.

Pension Grants.—Mr. F. O. ROBERTS informed Mr. Womersley, on March 10th, that in the last three months 117 awards had been made in respect of applications for pension grants submitted more than seven years after the men's discharge. In addition, treatment had been provided in 14 cases.

Notes in Brief.

The total amount of reserve funds possessed by approved societies under the National Health Insurance Acts was £115,500,000 on December 31st, 1929.

The total number of men insured under National Health Insurance in the United Kingdom was 9,191,800 in 1912, and 16,307,700 in 1928; of women, 3,845,600 in 1912, and 5,489,900 in 1928.

Miss Lawrence, in reply to a question, stated, on March 11th, that the deaths registered in England and Wales as due to cancer in 1915 numbered 39,847; that each following year showed an increase, the total for 1929 being 56,896.

Medical News.

THE St. Patrick's Day dinner of the Irish Medical Schools' and Graduates' Association was held at the Savoy Hotel, London, on March 17th, with Dr. W. Playfair Kennedy in the chair. Dr. W. Mulhall Corbet proposed the health of "Our Guests," and welcomed the presence of Mr. Cecil B. Harmsworth and Mrs. Harmsworth. In his reply Mr. Harmsworth referred appreciatively to his connexion with Trinity College, Dublin, and to the merits of Ireland as a resort for those interested in fishing. Lieut.-General H. B. Fawcus, D.G.A.M.S., proposed the toast of "The President of the Association," commenting on the support given in past times to the Royal Army Medical Corps by Irish medical graduates. The president responded, and contributed an account of the formation of the association at the time of the Annual Meeting of the British Medical Association at Bath in 1878. Much-appreciated musical items were contributed by Miss Peggy Hearn and Mr. Patrick Hughes, Mrs. A. P. Hughes accompanying at the piano. Towards the conclusion of the dinner the "Irish nightingale," Mrs. James Harold, delighted those present with her rendering of Irish songs.

AT a conference on birth control, to be held at the Central Hall, Westminster, on Friday, April 4th, the problem will be considered in relation to population, maternal health, and public health. At the morning session Mr. Harold Wright (editor of *The Nation*) will address the conference on birth control and the population problem; and Mr. Harold Chapple, F.R.C.S., will open a discussion on birth control in its relation to maternal health. At the afternoon session Dr. Maitland Radford, medical officer of health, Shoreditch, will open a discussion on birth control and public health authorities; and a resolution will be put to the conference urging the Ministry of Health and public health authorities to make available medical information on birth control to married people who ask for it. Tickets (1s. each) and further particulars may be obtained from the secretary, Committee for Birth Control Conference, 9, Parliament Mansions, Westminster, S.W.1.

THE presidential address entitled "The disastrous influence of a declining birth rate on the life of the nation," delivered by Dr. F. J. McCann at the annual meeting of the League of National Life held at Caxton Hall, Westminster, on October 30th, 1929, has now been published in pamphlet form, and may be obtained (price 6d. net) from Messrs. Roffey and Clark, Ltd., 12, High Street, Croydon.

A MEETING of the British Institute of Radiology, with which is incorporated the Röntgen Society, will be held at the rooms of the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, on March 30th, at 6 p.m., when Dr. Bernard Leggett will read a paper on the medical and surgical applications of electricity. A meeting of medical members of the institute will be held on the following afternoon at 32, Welbeck Street, at 5 p.m., when reports on cases of thoracic disease and other topics of interest will be welcomed. A general meeting of the Society of Radiographers will be held at the house of the British Institute of Radiology (32, Welbeck Street), on March 19th, at 7 p.m., when Dr. L. A. Rowden will read a paper entitled "Radiography—old and new."

THE annual meeting of the National Council for Mental Hygiene will be held to-day (Friday), March 21st, at 5 p.m. in the Hall of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1.

AT the first meeting of the National Safety Week Council on March 4th, under the chairmanship of Sir Gerald Bellhouse, further arrangements were made for inviting the co-operation of various societies and organizations concerned directly or indirectly in promoting the objects of Safety Week, which is being held this year from May 19th to 24th. The British Medical Association is represented on the council.

THE annual meeting of the Society for the Study of Inebriety will be held at 11, Chandos Street, W.1, on Tuesday, April 8th, at 4 p.m., for the election of officers, and to receive the report of the council and the financial statement. At the conclusion of the business Dr. Percy C. Barham will open a discussion on the difficulties of the institutional treatment of alcoholism and drug addictions.

THE Fellowship of Medicine announces that Mr. A. Tudor Edwards will lecture on modern surgical developments in chest disease at the Medical Society lecture room, 11, Chandos Street, Cavendish Square, W.1, on Tuesday, March 25th, at 4 p.m. Mr. Max Page will give a special demonstration on Thursday, March 27th, at 2 p.m., at the Victoria Hospital for Children, Tite Street, S.W.3. The lecture and demonstration are free to medical practitioners. From March 24th to April 12th a special course in medicine, surgery, and gynaecology will be held at the Royal Waterloo Hospital, Waterloo Road. The whole of each day will be occupied with operations, lectures, and clinical demonstrations in the wards and out-patient departments. From March 31st to April 5th a special all-day course in gastro-enterology at the Prince of Wales's Hospital, Tottenham, will deal with the medical and surgical aspects of the subject. Copies of all syllabuses and details of the general course of work in the fifty associated London hospitals may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A CLINICAL post-graduate course in otology, rhinology, and laryngology will be held at Bordeaux from June 30th to July 12th, under the direction of Professor Portmann. Lectures and demonstrations will be given daily, and there will be opportunity for individual tuition in the various methods of examination and treatment. The fee is 300 fr., and inquiries should be addressed to the secretary of the Faculty of Medicine, Bordeaux.

THE KING has appointed Dr. J. L. Margetson, medical officer District No. 1, Montserrat, to be an official member of the Executive Council of the Presidency of Montserrat.

THE forty-third congress of the Société d'Ophtalmologie will be held at the Paris Faculty of Medicine on May 12th, when a discussion, introduced by MM. Duverger and Velter, will be held on the biomicroscopy of the lens in health and disease. During the congress visits will be paid to hospitals and laboratories, and there will be an exhibition of optical and surgical instruments at the Faculty. Further information can be obtained from the general secretary, Dr. René Onfray, 6, Avenue de la Motte Picquet, Paris VII.

IN intimating his resignation as an alderman of the Blackburn Town Council, of which he has been a member for thirty-four years, Dr. J. T. T. Ramsay, J.P., has stated in a letter to the mayor that his decision is a consequence of the passing of the Local Government Act, 1929, which, by transferring the work of the Board of Guardians to the Town Council on April 1st next, had made it necessary for him to decide whether to continue as a member of the Council or surrender a part of his professional duties. Dr. Ramsay was mayor of the borough from 1922 to 1924, and has been a borough magistrate for the last twenty-five years. He was closely associated with the introduction and development of the local school medical service. In 1926 he became a co-opted member of the Mental Deficiency Act Committee.

THE Italian Travel Bureau in London (16, Waterloo Place, S.W.1) has issued a new pamphlet, with coloured illustrations, describing briefly the spas of Italy. The bureau has also published an illustrated souvenir booklet on the Italian Art Exhibition at Burlington House, and a handbook of the holiday courses for 1930 organized by the Italian Inter-University Institute, with lists of hotels in all parts of Italy.

THE Department of Health for Scotland has appointed Peter L. McKinlay, M.D.Glas., to be a medical officer in the department. Dr. McKinlay was assistant medical statistician to the Scottish Committee upon problems of child life, and for the last five years he has been medical statistician on the staff of the Medical Research Council.

DR. ALEXANDRE GUÉNIOT, who was born in 1832, has recently celebrated the fiftieth anniversary of his election to the Académie de Médecine in the obstetrical section. He was president of the Société de Chirurgie in 1882, of the Société Obstétricale et Gynécologie de Paris in 1888, and of the Académie de Médecine in 1906.

DR. JAMES MCALISTER RAMSAY of Oakley and Dr. Fraser McEwen Sinclair of Glencraig have been appointed to the Commission of the Peace for Fifeshire.

THE National Baby Week Council has recently added a new publication to its list, entitled *Functional Disorders of the Nervous System*, by Dr. Eric Pritchard, chairman of the executive committee. Copies, price 2d., may be obtained from the secretary of the council, 117, Piccadilly, W.1. A lantern lecture on rickets and other common nutritional disease has also been prepared, price 6d.; slides may be hired.

DR. A. BARDELAC DE PARIENTE has been nominated professor *honoris causa* of the Rubio Post-Graduate Institute at Madrid.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963,* and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh)

QUERIES AND ANSWERS.

MENOPAUSAL VASOMOTOR DISTURBANCES.

"D. J." inquires if any reader can suggest a proved remedy for the vasomotor disturbances of the menopause.

A FORM OF NARCOLEPSY.

DR. J. B. DAVIDSON (Northumberland) invites suggestions for the treatment of a female patient, aged 32 years, who has suffered from a form of narcolepsy for the last eleven years. Immediately the patient tries to do needlework, knitting, or darning she begins to fall asleep. During the period of recovery she has been known to cut the stockings she has been knitting. On another occasion she visited the grave of a relative, and while arranging flowers upon it fell asleep on the kerb of the tombstone.

TREATMENT OF ASTHMA.

"M. E. P." (South Africa) has a case of idiopathic bronchial asthma which has resisted every type of treatment, including morphine and its derivatives (which constantly produce sickness), adrenaline, inhalations (which cannot be tolerated), atropine, and ephedrine (hypodermic and oral). The patient is a woman aged 40, and an attack occurs regularly once a month (no relation to the menstrual cycle), having a variable duration from three to fourteen days. During the attack there is marked dyspnoea, cyanosis of the lips, and great distress. Adrenaline (10 minims) every hour, and sometimes every half-hour, gives practically no relief. Can anyone advise any form of treatment which might relieve this unfortunate woman?

GLASS PERMEABLE TO ULTRA-VIOLET RAYS.

DR. J. N. DYSON writes: Mr. Pilkington's arguments (March 8th, p. 478) as to the relative wave-lengths of 3,100 A.U. and 3,200 A.U. are entirely beside the point. The question at issue concerns the *amount* of rays; if their amount is infinitesimal, their length does not matter. With regard to his statement that artificial silk is permeable to the rays, I agree that a *thin* layer of this silk does not cut off all ultra-violet rays, but I need hardly add that most people who instal vita glass do not spend the day clothed in one thin layer of artificial silk. Ordinary clothing certainly prevents any rays from reaching the skin. Eidinow and Hill proved by their researches *not*, as stated by Mr. Pilkington, "that an area represented by face and hands is sufficient to give a result beneficial," but that an area equal to one-sixth of the body (and therefore greater than that of the hands and face), must receive at least an erythema dose, in order to increase the bactericidal power of the blood. Less than this, they proved, not only did not increase this power, but actually decreased it. Mr. Pilkington also seems to ignore the effect of the infra-red or heat rays on the skin of the face and hands. The only method of getting beneficial results from ultra-violet rays is by giving carefully measured and graduated doses to suit the individual requirements.

INCOME TAX.

Depreciation of Cars.

"Q. R. Q." asks for our views as to the proper rate of depreciation to be allowed for cars used professionally.

*** It is important to remember that the deduction allowed by the Income Tax Acts is for depreciation arising through *wear and tear*. For instance, there is no allowance for any loss which the practitioner may consider he has incurred through a reduction in value of his car through any other cause—for example, because a similar car may now cost less to buy than the one in use did originally. Further, the wear and tear allowed for is that of the car as a whole—replacements of parts, general overhaul, etc., can be charged as expenses provided that they do not destroy the identity of the car. Setting these questions aside, however, it is clear that the wear and tear to which a car is subjected shortens its life by bringing nearer the time when replacement becames economically desirable. It is, of course, obvious that the annual rate—on a "written-down" basis, as in the case of all such rates—depends in any particular instance on all sorts of factors—nature of the roads covered, degree of competence and care used in driving and looking after the car, whether the car is built to last, and so on. In such circumstances it is not surprising to find some variety in the rates allowed by the District Commissioners, who are the judges in the last resort on such questions. The two common rates are 15 per cent. and 20 per cent., and, in our opinion, the latter is usually more likely to be correct; on the written-down basis the value of a car will be reduced by the 20 per cent. allowance to 40 per cent. of its cost after four years, a figure at which most practitioners would be only too glad to dispose of a four-year old car. Practitioners should always make a point of claiming "obsolescence" allowance when replacing a car. Briefly that allowance represents the cost of replacement less the amount already allowed in respect of the depreciation of the car replaced. Consequently that claim when made puts right any insufficient depreciation allowance by reducing what would otherwise have been a greater sum to be deducted in calculating that allowance.

LETTERS, NOTES, ETC.

PNEUMOCOCCAL CEREBRO-SPINAL MENINGITIS.

DR. A. S. GUBB (Algiers) writes: A woman in her ordinary good health took the night train to Algiers (sleeping car) at 8 p.m.; at 4 a.m. she had an attack of nausea and sickness, and became very ill. On arrival at Algiers in the forenoon the right side of the face was paralysed, the features being drawn to the left; she was aphasic and unable to swallow. The right pupil was dilated and very sluggish, and the tongue was thickly coated. Her temperature was 103° F., and she was restless, but, as far as one could judge, not in pain. The bowels were confined, and were with great difficulty evacuated. As she had not micturated for several hours a catheter was passed, withdrawing 17 oz. of dark urine, which contained neither albumin nor sugar. There was no paralysis of the limbs, and the reflexes were normal. In the course of two or three hours she developed stiffness of the neck and Kernig's sign. Lumbar puncture gave exit to a turbid fluid obviously containing pus. As it appeared to be a case of ordinary cerebro-spinal meningitis, 60 c.cm. of antimeningococcal serum was forthwith injected into the spinal canal. Microscopical examination of the fluid (smear) showed a striking abundance of pneumococci; the field was paved with them. Antipneumococcal serum was then injected subcutaneously, but she became comatose and died on the second day after admission to hospital. The temperature remained high. As this inevitably fatal form of meningitis is by no means common, I thought it might be worth while to place these brief notes on record.

FREEDOM FROM RECURRENCE AFTER OPERATION FOR MALIGNANT DISEASE OF THE NOSE AND THROAT.

DR. ALBAN EVANS (Swansea) writes: The report of the meeting of the South Wales and Monmouthshire Branch in the *Supplement* of March 15th (p. 86) describes five cases shown by me of malignant disease of the nose and throat after operation. The interval of freedom from recurrence is not given in detail; as this is all-important, I shall be obliged by the publication of the operation dates of the cases in question.

E. E., epithelioma of left vocal cord; thyrotomy August 24th, 1928. Has a good voice.

S. B., epithelioma of right vocal cord; thyrotomy, December 7th, 1928. Has a good voice.

G. R., lymphosarcoma of right tonsil; operation, January 16th, 1929; radium a fortnight later.

A. T., epithelioma of right antrum and ethmoid; Moure's operation November 26th, 1929.

H. R., epithelioma of soft palate, left tonsil, and tongue; ligature of external carotid and internal jugular, and glandular dissection on January 21st, 1929; a week later the whole growth was destroyed by diathermy. On August 7th, 1929, a single gland was removed.

CHRONIC PLUMBISM.

DR. K. WATMAN (Worcester) writes: The case described briefly below is interesting because the lead limited its toxic action to the peripheral nerves (neurotropic), and also because the white cells were affected before the red cells—that is, there was no punctate basophilia. The patient is aged 48, and has worked for the last thirty-four years as a plumber. Twelve months ago had attack of herpes zoster. He now complains of lancinating pain in left shoulder, radiating down the arm to the fingers. No constipation; no colic. On examination of left arm there is marked weakness in the extensors of the wrist, wasting of extensor muscles of forearm, and marked wasting of muscles in thenar and hypothenar eminences. Sensation normal. Right arm not affected. Examination of teeth shows blue line at junction of gums and teeth, in some places continuous, in others punctate. There is no anaemia, no arterio-sclerosis, and no headache. The blood was examined at the Shire Hall by Mr. Duncan, and showed no change in the red cells—that is, no anaemia, no punctate basophilia. The white cells were 12,187 per c.mm., and differential count showed polymorphs 49 per cent., lymphocytes 46 per cent., hyalines 4 per cent., eosinophils 1 per cent. The teeth were extracted and tested for lead at the Shire Hall. They were found to contain 0.3 per cent. of metallic lead. X-ray examination of left shoulder show osteo-arthritis.

POPULATION AND FOOD SUPPLY.

DR. BINNIE DUNLOP (London, S.W.7) writes: From your notice (March 8th, p. 454) of the public health report for the Central Provinces of India one learns that strenuous efforts are being made to reduce the very high infant death rate. So I should like to point out that if these efforts be successful, there will follow a secondary result which, if observed, may cause surprise. As the birth rate is high and the food supply is increased very slowly, if at all, population is pressing heavily upon the food supply. Therefore only an improvement in the ratio between this and the number of mouths can reduce the general death rate, and a reduction of the infant death rate will raise the mortality among the older individuals.

RETENTION OF URINE DUE TO FAECAL IMPACTION.

DR. MARGARET G. JONES (Ramnad, South India) writes: In the *Journal* of December 28th, 1929 (p. 1198), Dr. J. Myles Mitchell comments on the rarity in a male child of urinary obstruction caused by faecal impaction. In this part of India such cases are not rare. The fruit of the prickly pear, used for hedges, contains stony, hard, indigestible seeds. Children commonly eat the fruit and get rid of the seeds in the bulky soft stools resulting from their vegetable diet. But if there is constipation the whole mass of faeces and seeds may accumulate for four or five days, and in the state in which the children are brought to us can only be removed by breaking up the mass digitally. These children, as we see them, have always obstruction of urine, and we are unable to pass a catheter. One boy was so much distended that bladder puncture by trocar was necessary to avoid rupture during removal of the impacted mass. In the out-patient department of this hospital of thirty beds we see seven or eight cases in a year, and in one series of twelve there were five boys and seven girls.

DISCLAIMER.

DR. D. DRYSDALE ANDERSON wishes to disclaim any authority for the account in the *Daily Chronicle* of March 14th of certain work being carried out by him and other colleagues.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 46, 47, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 95.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

275. Psittacosis.

MARCKS (*Zeit. f. Medizinalbeamte*, January 15th, 1930, p. 54) records an outbreak of seven cases of psittacosis in Berlin in the household of a professor who had just returned from Brazil with four parrots, three of which had died. In all the patients typhoid symptoms developed after a sudden onset of high fever; in one instance the incubation period was only three days. Pneumonia developed in all the patients at an early stage, but none had any cough or expectoration. In no instance was there any interhuman transmission of the disease, but all the patients had come in direct contact with the parrots. The disease ran a much milder course in the younger patients, aged 11 and 19 respectfully, than in the others. In the two fatal cases the necropsy showed that double pneumonia was the cause of death. Marcks concludes that this outbreak shows that special precautions should be taken with regard to parrots which have just been brought into the country, especially from America. Unnecessary contact with parrots should be avoided, and the bodies of birds suffering from diarrhoea should be burnt as well as their cages. All parrots coming from America should be medically examined and kept in quarantine before they are put on the market.

276. Endocrine Arthritis.

G. RIEBOLD (*Münch. med. Woch.*, January 17th, 1930, p. 90) considers that attacks of arthritis may arise from endocrine reactions, and divides these cases into two groups. The most frequent form of endocrine arthritis occurs at the climacteric, the period of subsiding ovarian activity. In this group the big joints, especially the knee-joints, are attacked. The condition is also without doubt to be traced to a hypofunction of the thyroid gland; many of these cases are cured by the administration of thyroid preparations. The second group of arthritis occurs in younger persons, at a time of great ovarian activity. In these cases the small joints of the fingers and toes are affected, and if the condition is of long duration there may be extension to the other joints. The attacks often pass into feverish bouts which are connected with the menstrual periods, or are associated with irregular menstruation. These patients are occasionally cured by the administration of ovarian preparations, and the attacks are probably in some way connected with disturbances of ovarian function, either hypofunction, dysfunction, or hyperfunction.

277. Bronchiectasis and Abscess Formation.

É. SERGENT (*Rev. Méd. Française*, January, 1930, p. 17), while stressing the importance of radiographic examinations aided by lipiodol in conditions associated with bronchiectasis, defines certain limitations to the method. In the first place, lipiodol injections cannot delineate the whole bronchial tree; 2 to 3 litres would be required for this. Areas of lung affected by atelectasis or sclerosis are cut off from its infiltration, and it is necessary to make films both before and after injection to avoid the deceptive indications of cavity formation sometimes given by lipiodol alone as the result of its infiltration of sclerosed peribronchial tissue surrounded by normal lung tissue; it is also possible to mistake the saccular dilatations due to emphysema for peribronchial abscesses. Chronic abscess cavities are shut off from penetration, and except where gangrene has supervened, with its characteristic fetid sputum, a large cavity delineated by lipiodol is usually bronchiectatic; finally, a large single cavity may be simulated by the superimposition of multiple smaller dilatations; hence the necessity of checking the result by stereoscopic radiography. Bronchiectasis may be secondary to abscess formation as the result of fibrotic traction, and the gradual evolution from the cylindrical to the saccular type may be followed by repeated examinations; such cases should receive early surgical treatment. It may be associated with abscess formation in the two following syndromes. (1) Bronchiectasis may supervene on the delayed resolution of broncho-pneumonia; here again the evolution from the cylindrical to the saccular type may be watched, and in some cases where the infective process is more acute there is not only weakening, but actual destruction of the bronchial walls, peribronchial abscesses being shown by small areas of deep opacity. (2) Pulmonary abscess and gangrene may both supervene on chronic bronchiectasis; again it must be remembered that abscess cavities show smooth rounded walls and are usually impermeable to lipiodol, whereas gangrenous areas are permeable and have ragged irregular walls. A condition described by American authors, where the evolution of bronchiectasis and abscess is simultaneous, is more rare, but where this occurs there is usually a lobar limitation. Bronchoscopy with aspiration is not dangerous, except in cachectic or cardiac subjects. It permits drainage when the natural outlet is insufficient, and it gives a chance of cure where areas of suppuration are recently developed. It may have radical effects in recent abscess formation and in the bronchiectasis following subacute broncho-pneumonia; in more long-standing cases it has only a palliative effect, though this is often much appreciated by patients with fetid expectoration. Most abscesses in the lung cortex are best treated surgically. It is most important not to wait for chronicity to develop before treatment is begun.

278. Communicability of Rheumatic Fever.

J. C. HATHAWAY (*Minnesota Med.*, January, 1930, p. 37) discusses rheumatic fever as a communicable disease from observations on 32 cases of acute rheumatic fever among students at Minnesota University. They were studied as two separate groups because more data were available from a recent epidemic. Nineteen cases (60 per cent.) occurred among a relatively small segregated group in the Agricultural Campus, comprising less than 10 per cent. of the University enrolment; Hathaway thinks that this strongly indicates that communicability must have been an important factor. Tonsils or teeth are regarded as the foci of infection, and tonsillitis or sinusitis is believed to initiate the attack and to be the probable portal of entry. Foci of infection were found in 69 per cent. of the cases; 85 per cent. occurred during the first four months of the year. Although the disease may occur at any age, the highest incidence appears to be from 10 to 20.

Surgery.

279. Staphylococcal Septicaemia.

I. M. WOOLLEY (*Arch. of Ped.*, December, 1929, p. 741), who records an illustrative case, states that this condition is most frequently due to *Staphylococcus pyogenes aureus*, but *Staphylococcus albus* and *citreus* are sometimes responsible. It is not limited to age, sex, or race, and has no seasonal preference. It usually occurs alone, but may be associated with other blood infections. Boils or carbuncles are the most frequent source, but abrasions, burns, infections of the ear, sinuses, and other body cavities are sometimes causal factors. The incubation period ranges from a few hours to several weeks. The onset is sudden, with chills, profuse sweating, and generalized muscular soreness; there is at first a moderate anaemia, which later develops into a severe secondary type. The stools frequently contain large numbers of the causal organism, especially when the infection is of gastro-intestinal origin, as in diseases due to infected raw milk. The skin soon shows many changes, such as multiple petechiae and superficial and deep abscesses. The skeletal muscles, joints, and bones, especially the femur, tibia, and humerus, are often involved, and spontaneous fractures may occur. Necropsies have shown that any organ in the body may be involved. The prognosis is always grave, the mortality being over 50 per cent. in cases originating from boils or carbuncles. Woolley's patient was a girl, aged 5, who, as the result of a boil on the left buttock, developed suppurative arthritis of the hip, multiple cutaneous abscesses, and osteomyelitis of the right femur; *Staphylococcus albus* was the responsible organism. Recovery finally followed the employment of vaccine therapy, cod-liver oil, ultra-violet light, and parathyroid with calcium lactate.

280. Haemangiomas of Muscle.

J. S. DAVIS and E. A. KITLOWSKI (*Arch. of Surg.*, January, 1930, p. 39) define haemangioma of muscle as a tumour of more or less extensive vascularity due to malformation and proliferation of the pre-existing vessels of the muscle. A simple angioma, by which is meant haemangioma of the muscle as distinct from lymphangioma, is probably a stage in the growth of these tumours towards the cavernous type. It is suggested that haemangiomas originate in a congenital anomaly, with trauma as a secondary factor causing growth, the congenital basis being limited to a certain district of the vascular network. Growth of these areas varies and may start at birth, or may be delayed until later life. The movements of the muscle may be an irritant causing growth, which may also be stimulated by an inflammatory reaction following

infection. Pain, which is caused by pressure of the tumour on a nerve trunk or by involvement of a nerve in the tumour itself, is the chief symptom, and occurs in the majority of cases. It is more intense when the angioma is in the long narrow muscles of the limbs than in the muscles of the head and trunk, and ceases directly the tumour is removed. Angiomas may cause numbness, formication, burning or pricking, and in many cases there is impairment of function due to the destruction of muscle tissue and the formation of tumour tissue and fat. Diagnosis is difficult owing to the indefinite symptoms, and is seldom made before operation. Angiomas are benign tumours with malignant tendency; they infiltrate the muscles, penetrate the aponeurosis and other tissues, and may invade the bone, growth being by infiltration, not expansion. An angioma infiltrates the adjacent tissue by small endothelial germs which give rise to the formation of capillaries. The interstitial connective tissue is invaded by endothelial cells forming capillaries which destroy the muscle and give place to the characteristic fenestrated tissue; development proceeds by multicentric proliferation. The employment of electrolysis, *x* rays, and radium has met with some success, but complete or partial excision is the most satisfactory method of treatment. In circumscribed angiomas excision of the tumour is sufficient, but in diffuse angiomas a good margin of healthy muscle must be removed with the tumour to ensure a permanent cure. It is only in extreme cases that amputation of the affected limb is necessary.

281. Sodium Chloride in the Treatment of Varicose Veins.

M. G. GILLESPIE and W. G. STROBEL (*Minnesota Med.*, January, 1930, p. 34) summarize their results and technique in 405 injections in 81 cases of varicose veins and ulcers during 1929, a 20 per cent. solution of sodium chloride being the only sclerosing agent used. The injections were given at three- to ten-day intervals over a period of from six to twelve weeks. With the patient seated on the end of the table and the feet resting on a stool the site of injection is located, and, after application of a tourniquet, the patient lies flat with the leg elevated to the level of the body. Usually the lowermost part of the varix is selected and sterilized; a 20 gauge needle is inserted, and blood is aspirated into the syringe, which contains 10 c.cm. of the salt solution. With the needle definitely in the lumen of the vein the leg is raised slightly higher than the body; after releasing the tourniquet the solution is slowly injected, care being taken that none escapes into the perivascular tissues. After withdrawal of the needle the leg is kept elevated; the site of the injection is compressed by gauze, and an elastic bandage is applied from the foot to above the knee. The authors state that 20 to 30 c.cm. may be injected at a time; if only 5 or 10 c.cm. are introduced, three or four injections may be made at one sitting. The authors claim that sodium chloride solution produces a more adherent and extensive thrombosis and a better end-result than other sclerosing agents. The only objections to its use are the possibility of sloughing if any of the solution escapes outside the vein wall, and that in most cases a cramping pain lasting from one to two minutes follows the injection.

282. *Alcohol Injections in Thoracic Surgery.*

G. LABAT (*Surg., Gynecol. and Obstet.*, January, 1930, p. 74) calls attention to the value of alcohol injections for the relief of post-operative pain and intercostal neuralgia, which are often sequels of thoracoplasty. Injection in the intercostal space is of little value, the only practical method being that of paravertebral block with injections close to the spinal column; it is sometimes necessary to inject one nerve above and one below those already injected. Injection of 3 c.cm. of 95 per cent. alcohol in the neighbourhood of each nerve is sufficient, and gives deeper and longer anaesthesia than when 80 per cent. only is used. Wheals are raised with 0.5 per cent. neocaine solution opposite the spinous processes at a distance of 4 cm., and through these the injecting needle is introduced toward the stump of the resected rib, with which it comes in contact at a depth of from 2 to 3 cm. After partial withdrawal the needle is reintroduced downward, inward, and forward, 45 degrees in all directions, until its point is 2.5 cm. deeper than the point at which contact was made, and the injection is made without displacing the needle. In thoracoplasty anaesthesia may be expected to last for months, and possibly until nature has provided adequate protection against irritation by the tube, but should this not be the case, reinjection could be adopted. Injection of the brachial plexus can be made with weak concentrations of alcohol without marked impairment of the motility of the upper extremity. In involvement of the entire plexus it can be injected with alcohol and neocaine in certain proportions, since they have a greater affinity for sensory than for motor nerves. Other post-operative neuralgias can be similarly greatly benefited by alcoholization of the affected nerves.

Therapeutics.

283. Ephedrine in Poliomyelitis.

M. B. BRAHDY and I. H. SCHEFFER (*Arch. Int. Med.*, January, 1930, p. 102) recall that in poliomyelitis the most important lesions occur in the central nervous system, and remark that unless the disease process is checked the meningeal irritation is followed by involvement of the nerve tissue proper. The initial toxic reaction causes an injurious hyperaemia and oedema in the cord and brain stem. This results in a local increase in pressure and an anoxaemia, which impair the function and injure the nerve cells. The rapid relief of this local reaction is of paramount importance. If the diagnosis of poliomyelitis is made in the preparalytic stage, the patient should be given convalescent serum. After the first paralysis appears serotherapy is of no avail, and treatment must be instituted to relieve the damaging local reaction in the central nervous system by diminishing the hyperaemia and oedema. In 1916 Meltzer tried epinephrine in a series of cases, and eight years later ephedrine was recommended by the medical profession. The latter drug, in contrast with epinephrine, has a less intense and more prolonged vasoconstrictor action, and is not followed by a secondary vasodilatation. Its intrathecal administration seems, therefore, to be a rational treatment in poliomyelitis. The authors describe their method of administering ephedrine; they give 40 to 60 mg. of an ephedrine salt in 1 c.cm. of sterile water and 2 to 4 c.cm. of spinal fluid. In severe cases it may be advisable to make two or more daily injections during the first few days. The results of this method in ten cases are given in detail; this small series included only bulbar cases, in all of which the patients were classified as being severely ill with a poor prognosis for life. Five died; but in a control group of similar cases the mortality was 75 per cent. The authors consider that the patients were benefited and the mortality reduced by the use of ephedrine, and that the results warrant the presentation of this preliminary report.

284. Dietetic Treatment of Tuberculosis.

E. MAYER and I. N. KUGELMASS (*Journ. Amer. Med. Assoc.*, December 14th, 1929, p. 1856) comment on the treatment of tuberculosis by Gerson's method, in which the diet contains but little sodium chloride, protein, and carbohydrate, though it is rich in fats and vitamins. They agree that an excessive calorie intake burdens the pulmonary mechanism, thereby preventing functional rest. Loss of mineral salts is repaired by a dietary rich in base-forming salts; sodium chloride is excluded because tuberculosis causes excessive tissue hydration. Much of the food is taken raw, and that which is lightly cooked is rich in vitamins; the authors consider that this marks a definite advance in the dietary of tuberculosis. The accelerating effect of vitamin D on calcium absorption in the intestinal tract helps to explain the healing of tuberculous intestinal ulcers. The authors report that twenty patients suffering from advanced refractory tuberculosis were kept for six months on a special diet equivalent to 3,500 calories; eight gained substantially in weight, and in ten instances the sputum decreased considerably, but tubercle bacilli continued present. Four patients became afebrile, while *two developed fever. Eight patients showed* definite physical improvement in lungs, and two with intestinal tuberculosis appeared to be cured; one did not improve. Alimentary disturbances, lassitude, and pain diminished. The acid-base equilibrium shifted towards the basic side. This effect was confirmed also by experiments on animals.

285. Urinary Antiseptics.

E. JAEGGY (*Rev. Méd. de la Suisse Romande*, December 25th, 1929, p. 857) emphasizes the fact that there is no panacea for urinary infections; salol and urotropine have proved disappointing, but a more intelligent understanding of certain aspects of urinary infection will make its treatment more practicable. The metastatic nature of these infections is frequently forgotten, and it is useless to give antiseptics until focal sepsis is eradicated; this applies more particularly to coccal infections. Urinary stasis must also be overcome, at whatever level it may exist, before antiseptic measures can be effective. A thorough bacteriological investigation is essential in every case of suspected bacilluria, a preliminary guide to which is the turbidity of the urine or its clearness; the administration of antiseptics, except as a prophylactic measure, is quite useless when the urine is clear. It is further essential, in the author's opinion, to determine the exact degree of acidity or alkalinity of the urine, and he recommends the routine use of aniline indicators instead of the less accurate litmus papers. All organisms found in urinary infections grow on an alkaline medium and are inhibited by an acid one, but it is possible for them to get acclimatized and to continue multiplying after the medium has turned acid; this is particularly the case with *B. coli*,

which produces an acid medium by its own chemical action. The key to success in treatment is to give the organisms no chance to become acclimatized to any one medium; after two or three weeks an acid medium should be changed to an alkaline, and vice versa, the change being accurately controlled by indicators. The reaction of the urine is much affected by diet; in general, fasting, with abundance of water, produces acidity, as does also a protein and fat diet, whereas a diet rich in milk, potatoes, and fruit has a reverse action. It is thus seen that Nature helps treatment in the first instance by destroying appetite and producing thirst by fever, which itself tends to produce acidity. In treating urinary infections by varying the reaction of the urine, full advantage should be taken of the dietetic methods. With regard to individual drugs and antiseptics, the beneficial effects of salvarsan and colloidol metals in staphylococcal infections is worthy of note. Urotropine is regarded as more of prophylactic than therapeutic value, but may be used as an adjunct to acidification; similarly, salol can be used with alkalinization, but the author prefers camphoric acid in doses of 4 grams a day, given in cachets of 0.5 gram; methylene blue he regards only as a vesical sedative. For lavage treatment silver nitrate is far more potent than any of the organic silver compounds; mercury oxycyanide, in a strength of 1 in 5,000, is much used in the Latin countries. Finally, there is some evidence that the natural metallic waters containing an infinitesimal proportion of dissociated metallic ions have a decided effect in inhibiting bacterial growth. The author has seen interesting demonstrations of the complete sterilization of ordinary tap water by mere contact with spongy silver (well known as a catalytic agent), and he suggests that there may be a future for the use in therapeutics of water thus treated with catalysts.

Disease in Childhood.

226. Anaemia Neonatorum.

A. GISMONDI (*Accademia Medica*, January 15th, 1930, p. 8) reviews the published cases of anaemia of the newborn infant and discusses a case observed by himself in the paediatric ward of the Samplerdarena civil hospital at Genoa. The infant's mother suffered from rheumatism and endocarditis. Records of the blood examination in all the cases under review show that under the title of "infantile anaemia" several different syndromes are described; the first division that has to be made is that of aplastic from regenerative anaemia. The case described by Gismondi belongs to the former type, and is the most dangerous. The author thinks that he can explain the occurrence of these two different forms of anaemia by taking into consideration the period of intrauterine life when the toxic stimuli act on the blood. In an early phase the aplastic variety occurs, while in a period nearer to birth the regenerative variety is concerned. The etiology—very difficult to ascertain in the majority of cases—was attributed in the present case to the rheumatic infection of the mother. Syphilis does not seem to be a cause of anaemia in the newly born. Treatment with liver extract was attended in Gismondi's case by most satisfactory results.

287. Chronic Diffuse Nephritis in Children.

ACCORDING to GLADYS L. BOYD (*Canadian Med. Assoc. Journ.*, December, 1929, p. 679) chronic diffuse nephritis is not rare in children; she discusses its course, prognosis, and treatment. Two main types of the disease are seen: those in which symptoms or signs, or both, follow an acute nephritis, and those in which no suggestive symptoms occur until the advent of chronic changes, and secondary arterio-sclerosis may be present. The acute cases most likely to become chronic are those in which both haematuria and oedema are present, indicating a diffuse renal lesion. Usually when symptoms persist longer than two months, or recur after a temporary cessation, the case has become chronic. Recovery may yet ensue, but in the less fortunate the disease passes into a subacute stage. Haematuria recurs frequently, the oedema persists, the renal function becomes progressively worse, sclerotic changes occur in the blood vessels, and death ensues from uraemia or an acute infection. The second type also comprises two groups of cases: those in which the disease is benign for years, and those in which symptoms of the end stage of the disease, such as uraemia and headaches, are first noted, and general arterio-sclerosis is present. In both groups vague symptoms of ill health and recurrent infections exist for some years. In the arterio-sclerotic cases death usually occurs within a few months, and infective foci are always found. The prognosis must be governed by the clinical history, signs, and symptoms, aided by the results of laboratory tests. The treatment is symptomatic except for the measures directed to prevention. All foci of infection (tonsils, adenoids, teeth) should be completely removed. Absolute rest in bed is essential during all exacerbations or acute attacks. Dietetic therapy is most important, and a suitable diet should be selected to give the most adequate rest to the kidney, to combat the secondary anaemia invariably present, and to afford sufficient nourishment. For the oedema, rest in bed, the smallest possible intake of fluid, and a salt-free diet are indicated. Saline cathartics and diuretics are often beneficial, with the addition of digitalis if cardiac weakness is present. Repeated abdominal paracentesis is often of value. Uraemia may be due to cerebral oedema or nitrogen retention; in every case an attempt should be made to rid the brain of excessive fluid. Two methods are available: the careful intravenous injection of a 1 per cent. solution of magnesium sulphate, and the slow withdrawal of cerebro-spinal fluid. Exsanguination transfusion has proved successful in a few extreme cases.

288. Coarctation of the Aorta.

A. P. THOMSON and F. W. M. LAMB (*Arch. Dis. Child.*, December, 1929, p. 377) report the case of a girl, aged 5 years, thin, but of fair health, with slight cardiac hypertrophy and a blowing systolic murmur audible all over the precordia, loudest at the base and conducted up into the vessels of the neck. A loud systolic murmur was also heard at the back in the interscapular area. The left hand as far as the wrist was uniformly dusky, blue, and congested, the right being normal. The pulsation in the femoral arteries was distinctly feeble. There was no evidence of a superficial collateral circulation. The tension in the brachial arteries was much above normal, the left being 200–220/160–190 mm., and the right being 175–215/120–145 mm. In the popliteal arteries the systolic pressure was 125 mm. The urine contained albumin, and the urea concentration, as estimated by the method of Calvert, was decidedly deficient. The child died from pneumonia and tonsillitis about six months after the first examination. At the post-mortem examination the aorta was found greatly constricted, but nowhere obliterated, from a point a little above the attachment of the obliterated ductus arteriosus, almost opposite the origin of the subclavian artery, to a considerable distance below, for a total length of 2 inches. Microscopically, there was arterio-sclerosis of the ascending aorta, of the stenosed area, where it was more marked, of the femoral artery, and of the left brachial artery. There was some fibrosis in the right kidney and a marked diffuse fibrosis in the left, the changes being so advanced as to suggest, as its basis, a congenital maldevelopment of the organ. Bonnet has described two main types of coarctation, the adult and the infantile. In the former there is an extension into the aorta of the special tissue of the ductus arteriosus, with subsequent contraction as the ductus is obliterated, the aorta appearing to be ligatured at this level. In the latter there is a failure of development of the isthmus of the aorta, the part that lies between the subclavian artery and the ductus arteriosus, and the stenosis is limited to that area. The authors consider that in the case under review the diffuse arterio-sclerosis in some way accentuated an original maldevelopment of the isthmus.

Obstetrics and Gynaecology.

239. Treatment of Placenta Praevia.

J. P. GREENHILL (*Surg., Gynecol. and Obstet.*, January, 1930, p. 113), reviewing the present-day treatment of placenta praevia, considers that all patients with a painless, causeless haemorrhage in the last three months of pregnancy should be immediately sent to hospital without a vaginal examination, and without being packed unless absolutely necessary; modern conditions of transport and accessibility of hospitals make it rarely necessary to treat the patient at home, or to pack the vagina prior to removal. Low cervical Caesarean section under local anaesthesia is advocated as being the best treatment in cases of central or partial placenta praevia, with amputation of the uterus, after removal of the baby, in infected cases. In central or partial placenta praevia with severe haemorrhage the abdominal route is said to be the best, regardless of the condition of the child, and to be the most certain way of delivering the baby alive. In the marginal condition, and for a certain proportion of cases of partial placenta praevia, the older methods with rupture of the membranes, with or without vaginal tamponade, Braxton Hicks version, and metreurysis, may be used. The more frequent employment of blood transfusion, repeated when necessary, is advocated. Although post-partum haemorrhage rarely follows the cervical Caesarean section, such a complication must be watched for, while sepsis is less frequent after laparotomy than after extensive vaginal manipulation.

290. Strangulation of the Cord by an Amniotic Band.

O. GOSSELIN (*Bruxelles-Méd.*, January, 1930, p. 292) reports a case of foetal death *in utero*, resulting from strangulation of the cord and stoppage of the circulation between placenta and child by an amniotic band. A 1-para, aged 30, had a good family history and was in perfect health; there was no history of miscarriage, and the Wassermann test was negative. Foetal movements ceased twenty-four days before the expected date of confinement, and when it arrived spontaneous labour occurred, a macerated child being born. A knotted amniotic band encircled the cord, interfering with circulation and causing foetal death by asphyxia. One end of the band was attached at a point 3 cm. from the placental insertion of the cord, while the other end had been swallowed by the child. Gosselin mentions that these bands are supposed to form between amnion and foetal ectoderm during the incurving developmental stage, in cases where the toxins of syphilis or alcoholism may be active. He believes that in the present case neither of these toxins was p[illegible]er, that these bands form from an [illegible] of the solid cellular bud from which the amnion is derived. Gosselin points out that in cases where the band is knotted one end must have become detached; that the knotting is very probably effected by foetal movements; and that for the knot to be drawn tight the band must become re-attached to another point. In his case that point was the mouth of the child.

291. Treatment of Submucous Myomata.

K. FINK (*Zentralbl. f. Gynäk.*, January 11th, 1930, p. 104), discussing the treatment of submucous myomata, states that from 1924–28 his series of 145 operations for uterine myoma included no fewer than 20.7 per cent. of submucous myomata; cases of small pedunculated tumours, extruded through the portio vaginalis, were excluded. He concludes that when treatment of submucous myomata presents technical difficulty cases in which preservation of the child-bearing faculty is of importance are few. Patients known to possess, in addition, intramural myomata should not be treated by enucleation from the uterine side; this is more dangerous than subtotal extirpation, and is not likely to preserve fecundity. The same may be said of those who possess children, and who, although still of child-bearing age, do not earnestly desire conservative treatment. After the menopause deep enucleation (per vaginam) of submucous myomata is fraught with considerable danger of perforation of the friable uterus. Vaginal enucleation should be reserved for gangrenous sessile submucous myomata in cases in which a demarcation line is in process of formation, and the tumour possesses some mobility with respect to the uterine wall. If the gangrenous myoma is tightly fixed, extirpation by the combined abdomino-vaginal route is indicated. In Fink's experience untoward results, such as infection, have not followed the use of the curette in cases of submucous myoma, but he refers to numerous instances in which the existence of the tumour has been overlooked during curetting.

Pathology.

292. The Endocrine Basis of Menstruation.

D. J. CANNON (*Irish Journ. Med. Sci.*, January, 1930, p. 3) considers that the relation between gynaecology and endocrinology is for all practical purposes a study of the menstrual function and its irregularities. An account of the menstrual process is given, and the views and work of such authorities as Frankl, Corner, Allen and Doisy, Schroeder, and Shaw are discussed. A description is given of haemorrhagic metropathia; this condition, which is now receiving attention, throws light on some of the problems of normal menstruation. Cannon summarizes this study of the menstrual process as follows. The alpha-hormone of the pituitary gland (present in the anterior lobe, and discovered by Weimas) activates follicle ripening. The follicles respond by manufacturing a hormone, oestrin or folliculin, which produces the gradual development of the endometrium which is characteristic of the interval phase of the menstrual cycle. The corpus luteum then secretes a hormone, perhaps qualitatively identical with, but quantitatively different from, the hormone of the ripening Graafian follicle. This hormone, together with the secretion of the thyroid gland, produces the full series of secretory and hyperaemic changes that characterize the early or secretory phase of pseudo-pregnancy. When the corpus luteum becomes fully matured, its luteinic portion, activated by the beta-hormone of the pituitary gland (the beta-hormone of Weimas and the special pituitary hormone), produces the final stage of pseudo-pregnancy or the menstrual decidua. The commencing degeneration of the corpus luteum, which normally synchronizes with the death of the ovum, is followed by decidual necrosis or menstruation. The special mechanism responsible for the menstrual rhythm has not yet been ascertained. Cannon believes that the normal rhythm, like the normal quantity of menstrual blood, depends upon no special mechanism or hormone, but rather upon the harmonious adjustment of all the ductless glands, the disturbance of any one of which will upset the menstrual rhythm. He suggests that, on account of the absence of a sexual cycle in the higher animals, ovulation and insemination occurring simultaneously, a monthly recurrence of ovulation is nature's method of securing fertility.

293. Spread of the Infectious Process in Poliomyelitis.

R. W. FAIRBROTHER and E. W. HURST (*Journ. Path. and Bact.*, January, 1930, p. 17) record a series of experiments on poliomyelitis produced in monkeys, the results of which do not accord with existing theories of the pathogenesis of the disease or with statements in the literature as to the regions of the nervous system from which the virus can be recovered. After intranasal and intracerebral inoculation in monkeys, poliomyelitis spreads histologically from above downwards, the various levels of the cord becoming involved more or less simultaneously. Owing to the greater susceptibility of the anterior horn cells, particularly of the lumbar region, paralysis usually appears, and later becomes complete, first in the legs; clinical findings are thus no guide to the path of entry or manner of propagation of the disease. Spread of the infection to the brain stem and cord occurs by way of the axis cylinders, and this appears to be the usual path to other parts of the central nervous system; passage along the meninges is, however, possible, and probably plays some part in the local dissemination of the infection. Meningitis is therefore not the first lesion to appear in the disease, which begins as a primary degeneration of nerve cells, accompanied by inflammation in the interstitial tissues. The virus is present in greatest amount in those regions in which nerve-cell degeneration is particularly severe—that is, in the spinal cord and brain stem; where this degeneration is slight, as in the cerebral cortex, in spite of numerous foci of inflammation, the virus is found inconstantly. The cerebral cortex is not a favourable site for survival of the virus. If the virus travels chiefly by way of the axis cylinders its appearance in the cerebro-spinal fluid would not be expected, nor is it found there except rarely.

294. The Action of Specific Diuretics.

As the result of a series of experiments on diuresis, G. M. CURTIS (*Journ. Amer. Med. Assoc.*, December 28th, 1929, p. 2016) offers an explanation of the mode of action of the specific diuretics which differs from currently accepted teachings. The clinical studies of Veil on diabetes insipidus have emphasized the importance of the state of the tissues in the phenomenon of diuresis. As the result of investigating various diuretics, Schlayer has noted that caffeine has an early extrarenal effect, and Keith and Whelan have concluded that the action of ammonium chloride and of the organic mercury compounds is not limited to the kidney, but that extrarenal factors enter into consideration. Experimenting with rabbits, Curtis found that a profuse diuresis rapidly followed administration of the diuretic. Subsequent to the injection there was a slight but definite rise in the whole blood chloride content. The rise may be slight, especially if it is associated with a rapid excretion of chloride by the kidneys. The urinary chloride becomes more concentrated even throughout the increasing diuresis, and the concentration of the electrolytes likewise rises and roughly parallels the chloride curve. The amount of sodium chloride excreted in fifty minutes was approximately a third of the entire blood chloride, and yet the latter was actually higher at the end of the experiment. It follows that, under the influence of the diuretic, chlorides rapidly leave the tissues, enter the blood stream, and pass into the urine. The conjecture that the chlorides play more than a passive part in diuresis was further strengthened by the observation that, in the experiments in which diuresis did not occur, the marked increase in chloride excretion also failed. This conjecture was also tested by injecting sugar solutions into the peritoneum. These rapidly acquired a concentration of sodium chloride; the whole blood chloride content fell, and water and sugar entered the blood stream. The chlorides were rapidly diverted from the blood, and eventually from the tissues. Thus the ordinary response to diuretics is definitely changed by intraperitoneal injections. These conclusions indicate that the primary action of the specific diuretics is on the tissues. Under their influence permeability changes are initiated, resulting in a rapid passage of electrolytes, principally chlorides, into the blood stream. These act as stimulants to the kidney and initiate the formation of urine. Associated with this action on the tissues is doubtless a similar one on the renal cells.

PNEUMONIA

Excellent results have been obtained in the treatment of Pneumonia with

OPTOCHIN BASE

(Ethylhydrocupreine Alkaloid)

★OPTOCHIN BASE (Howards) is a synthetic derivative of QUININE with a definite bactericidal action to all types of pneumococcus.

Given orally in tablets or powder, OPTOCHIN BASE (Howards) is well adapted for use by the General Practitioner and is of great value in Pneumonia of children and adults.

In 2-grain tablets and in powder.

RHEUMATISM, GOUT, NEURITIS, SCIATICA, LUMBAGO, etc.

Reports from eminent medical men show that

AGOTAN (HOWARDS)

BRAND

(Phenyl Cinchoninic Acid B.P.C.)

is remarkably successful in the treatment of Rheumatoid conditions due to excess of Uric Acid. Owing to the powerful elimination of Uric Acid **from the blood,** under the influence of Agotan, the deposition in joints, etc., is prevented or reduced, thus avoiding or **quickly removing** local manifestations.

In 7½-grain tablets, in powder, also in tubes for local application.

★ *Literature will be sent on request to the Manufacturers*

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms etc., apply to the Medical Superintendent*

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.

Telephone: Teignmouth 289.

The MAUDSLEY HOSPITAL
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841–2.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.

IN-PATIENTS: (*a*) 164 beds (both sexes) in wards or separate rooms. (*b*) 13 paying rooms (for ladies) with special sitting room, garden, and dietary.

Terms:

(*a*) **£5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.**

(*b*) **£6 6s. a week.**

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

WONFORD HOUSE HOSPITAL,
EXETER, DEVON.

Telegrams: Exeter 2642. *Telephone*: Exeter 2642.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as MEDICAL SUPERINTENDENT (Resident) at the DARENTH TRAINING COLONY, near DARTFORD, KENT. Candidates must be men under 40 years of age unless already in the Mental Hospital Service of the London County Council or of the Metropolitan Asylums Board, and must be registered to practise both in Medicine and Surgery in England. The position is pensionable. Salary £1,000 a year, plus fluctuating temporary additions, making the total remuneration at present about £1,205 a year, with unfurnished house (rates, taxes, and water supply free). The question of improvement of remuneration, upon consolidation of basic rate and temporary additions, is under consideration. Full particulars and conditions of appointment on form of application (on which alone application can be made) obtainable by sending stamped addressed foolscap envelope to the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Canvassing disqualifies. Applications must be received by Saturday, March 29th.

MONTAGU H. COX,
Clerk of the London County Council.

Westminster Hospital,

Broad Sanctuary, S.W.1.

EDWARD A. ATTWOOD, Secretary.

COLONIAL MEDICAL SERVICES.

Vacancies exist at present for Medical Officers in:—

(*a*) **THE WEST AFRICAN MEDICAL STAFF;**
(*b*) **THE EAST AFRICAN MEDICAL SERVICE;**
(*c*) **THE MALAYAN MEDICAL SERVICE.**

Qualifications.

Applicants must be British subjects of European parentage and between 22 and 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held hospital or public health appointments or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

Courses of Study.

Selected candidates will normally be required to take a special course of study in tropical medicine and hygiene either at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine, or at the University of Edinburgh, before taking up their appointments. Tuition fees and the usual training allowance will be paid from Government funds.

Further particulars and forms of application may be obtained, on application in writing, from the PRIVATE SECRETARY (APPOINTMENTS), COLONIAL OFFICE, 2, Richmond Terrace, Whitehall, London, S.W.1.

County Borough of Barnsley.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Council of the County Borough of Barnsley invite applications for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer at an inclusive salary of £600 per annum.

Candidates must be registered Medical Practitioners of at least three years' standing and should have had experience in the work of school medical inspection and maternity and child welfare. The possession of the D.P.H., and experience in ante-natal work, in the treatment of errors of refraction and in orthopædic work, will be considered additional qualifications.

The candidate appointed must devote his or her whole time to the duties of the office, will not be allowed to engage in private or consulting practice, and will work under the supervision of the Medical Officer of Health, who is also School Medical Officer.

Applications upon the prescribed form, which may be obtained from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), must be sent to me on or before April 8th, endorsed "Assistant Medical Officer of Health."

The appointment will be determinable by three months' notice on either side.

Town Clerk's Office, Barnsley. March 17th, 1930. A. D. MASON, Town Clerk.

County Council of the West RIDING OF YORKSHIRE.

MIDDLETON-IN-WHARFEDALE SANATORIUM.

The County Council of the West Riding of Yorkshire invite applications for the appointment of JUNIOR RESIDENT MEDICAL OFFICER at the Middleton-in-Wharfedale Sanatorium, near Ilkley (300 beds). The appointment will be for one year. Salary at the rate of £250 per annum, with board and laundry.

Applications, together with copies of recent testimonials, should be sent to the County Medical Officer, County Hall, Wakefield, not later than March 29th.

County Hall, Wakefield. March, 1930. J. CHARLES McGRATH, Clerk of the County Council.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

The Surrey County Council invites applications from registered male Medical Practitioners for the post of Assistant Medical Officer. Applicants must be over 35 years of age, and must possess the Diploma of Public Health. The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare and Tuberculosis Acts, and Venereal Diseases Regulations; and such other Public Health duties as may be allocated to him. The person appointed will be required to devote his whole time to the service of the County Council and reside in the County. The salary will be £600 a year, rising by annual increments of £20 to a maximum of £700, together with travelling expenses in accordance with the Council's scale.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained together with further particulars from the County Medical Officer, County Hall, Kingston-upon-Thames, to whom the completed forms should be returned not later than Saturday, March 29th. All communications must be endorsed "Assistant Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

County Hall, Kingston-upon-Thames. March 11th, 1930. DUDLEY AUKLAND, Clerk of the Council.

Connaught Hospital

(100 Beds)

FOR WALTHAMSTOW, WANSTEAD, AND LEYTON, Orford Road, E.17.

Applications are invited for the undermentioned posts:

SENIOR RESIDENT HOUSE SURGEON (R.M.O.) (male). Salary £150 per annum.
JUNIOR RESIDENT HOUSE SURGEON (male). Salary £100 per annum.

Appointments to date from May 1st, and to be for a period of six months, with board, residence, and laundry provided.

Applications, with three testimonials (or copies), should be sent to the Secretary, to reach him not later than April 16th.

County Borough of Stockport.

PUBLIC ASSISTANCE COMMITTEE.

RESIDENT ASSISTANT MEDICAL SUPERINTENDENT, etc. (Male).

Applications are invited from duly qualified Medical Practitioners for the position of Resident Assistant Medical Superintendent of the STEPPING HILL HOSPITAL, Assistant Medical Officer of the STOCKPORT POOR LAW INSTITUTION, and Assistant Medical Officer of the CHILDREN'S HOMES.

Salary £350 per annum, with the usual residential allowances.

The person appointed will be required to devote the whole of his time to the duties of the foregoing appointment, and will be under the general supervision of the Chief Medical Officer of the Public Assistance Committee.

The duties of the office are those prescribed by the Orders of the Ministry of Health and such regulations as may be made from time to time by the Town Council.

Applications, stating experience, accompanied by copies of three recent testimonials, are to be sent to the undersigned as soon as possible, endorsed "Resident Assistant Medical Superintendent."

By Order.

Union Offices, Shaw Heath, Stockport. March 17th, 1930. HARRY BARLOW, Clerk to the Committee.

Applications are invited from Practitioners resident within a suitable distance for the post of MEDICAL OFFICER to the MIDDLETON AND MACDONALD MEMORIAL CLINIC at 1, Ladbroke Square, and 92, Tavistock Road, W.11, for Children under five suffering from Malnutrition and Chronic Ailments.

Duties are: one session weekly for Out-patients; one session for L.C.C. Minor Ailments Treatment Centre; and one session per fortnight for the Ante- and Post-Natal Centre. Usual L.C.C. Clinic remuneration.

The officer will also share supervision of In-patients with two colleagues, in rotation, and for this a separate honorarium will be paid.

Applications should be sent to Hon. Secretary of the Clinic, 1, Ladbroke Square, W.11.

Hackney Hospital.

The Guardians of the Hackney Union invite applications from duly qualified gentlemen for the position of ASSISTANT MEDICAL OFFICER.

Candidates must be single, have held a previous resident Hospital appointment, and have had experience in Midwifery and Gynæcology.

The Hospital, which is situate at High Street, Homerton, E.9, contains 800 beds and is equipped with modern requirements.

Besides the Medical Superintendent, there are six Resident Medical Officer and a Clinical Pathologist.

The remuneration is at the rate of £350 per annum, rising £25 annually to a maximum of £375 per annum, together with rations, washing, furnished apartments, and attendance.

The officer appointed will be required to render assistance at the other establishments and departments of the Union, to assist in the training and instruction of nurses, and to devote the whole of his time to the service of the Guardians.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1896.

Further particulars as to the duties may be obtained from the Medical Superintendent.

Canvassing the Guardians directly or indirectly, will disqualify candidates.

Applications must be made upon forms which are obtainable from the undersigned. The forms must be completed and returned, with copies of not more than three recent testimonials, by March 28th.

By Order,
E. W. HARBOUR,
Clerk to the Guardians.

Clerk's Office,
Hackney Union,
2, Sidney Road,
Homerton, E.9.

Manchester Royal Infirmary.

HONORARY ASSISTANT SURGEON.

The Board of Management invite applications for the above appointment. Candidates must be Fellows of the Royal College of Surgeons of England, and are required to forward diplomas, original testimonials (not exceeding eight in number, and dated) and a certificate of age with their applications, by 9 a.m. on Monday, April 21st, addressed to the undersigned.

Candidates are required to furnish the Secretary with forty-five copies of their application and testimonials for distribution prior to the meeting of the Committee of Election.

Canvassing, directly or indirectly, is forbidden, and the Committee reserve to themselves the right, on proceeding to election, to take into consideration any complaint that canvassing on behalf of any candidate has taken place.

By Order,

ASSISTANT PATHOLOGIST.

An Assistant Pathologist is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than 30 years of age, and must hold qualifications in Medicine and Surgery of University standard; a D.P.H. and D.T.M. & H., though not essential, are desirable. Salary, Taels 650 per mensem, or Taels 700 per mensem if holding a D.P.H., under three years' agreement.

The agreement is renewable, in the event of *satisfactory services*, at a *triennial* increase of Taels 100 per mensem up to Taels 1,000 or Taels 1,050 per mensem if holding a D.P.H.

The Chief Pathologist, provided he holds the D.P.H., is eligible for the higher appointments of Deputy Commissioner and Commissioner of Public Health, the present maximum pay for which is Taels 1,350 and Taels 2,000 per mensem respectively.

First-class passage is given with half pay during voyage.

Eight months' leave is given on full pay, with first-class passage, after every period of five years' service *in Shanghai*.

Free medical attendance is provided, and there is participation in the benefits of a Superannuation Fund.

A Tael at the present rate of exchange equals about 1/11. Exchange is, however, subject to fluctuation.

Particulars of the appointment, and full details as to the benefits enjoyed by Municipal employees under their Terms of Service, may be obtained from Council's Agents.

Applications, in candidates' own handwriting, with full information as to their qualifications and experience, etc., accompanied by *at least* three recent testimonials, and endorsed "Assistant Pathologist" on the cover, should be forwarded to JOHN POOK & Co., Agent for the Municipal Council of Shanghai, 68, Fenchurch Street, London, E.C.3.

March, 1930.

The Government of Bengal invite

applications for an appointment as CHIEF SANITARY OFFICER for the ASANSAL MINING SETTLEMENT under the Asansal Mines Board of Health, Burdwan District, BENGAL.

Candidates must possess a diploma in Public Health and have had administrative experience in Public Health work. They must know or be prepared to acquire a knowledge of Hindustani. Age should not be under 30 nor more than 40 years. Agreement for five years. Rent free house. Pay, Rs.1,000 a month, rising by annual increments of Rs.75 to Rs.1,300 a month. In addition, overseas pay of £25 a month.

Free first-class passages out and home for officer and wife (*if married*). Sterling equivalent per annum of Rs.1,000, plus overseas pay £25, approximately £1,200; Rs.1,300 plus overseas pay £25, £1,470. (Return passage and overseas pay admissible only to an officer of non-Asiatic domicile.) Strict medical examination.

Forms of application and further particulars may be obtained upon request by post-card from the Secretary to the High Commissioner for India, General Department, India House, Aldwych, London, W.C.2. Last date for the receipt of applications April 10th.

Bolton Infirmary & Dispensary.

ALBERT E. BRISCOE, Secretary.

City of London Hospital for

DISEASES OF THE HEART AND LUNGS, Victoria Park, E.2.

(Bus, Tram, and Rail, Cambridge Heath, L. & N.E. Railway.)

A vacancy for a HOUSE PHYSICIAN (male) will occur on May 1st. Six months' appointment. Salary at the rate of £100 per annum. Board, residence, and laundry provided.

Applications, with copies of three testimonials, should be sent to the undersigned on or before Monday, April 7th.

GEORGE WATTS, Secretary.

County Council of Durham.

VENEREAL DISEASES MEDICAL OFFICER.

The County Health Committee invite applications for a Clinical Venereal Diseases Medical Officer at a salary of £750 per annum, rising by three biennial increments of £50 and a further one of £37 10s. to a maximum of £937 10s. per annum. Travelling expenses will be paid by the County Council.

The appointment is terminable by *three months' notice on either side*, and will be subject to the following conditions:

1. The officer appointed must be a registered Medical Practitioner, with not less than three years' experience in the practice of his profession subsequent to qualification, must devote the whole of his time to the duties of the office, and must not engage in private practice.
2. Applicants for the post of Venereal Diseases Medical Officer must comply with the following conditions which are laid down in Section 5 of the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, made by the Minister of Health under Section 59 of the Local Government Act, 1929:

   "Any person appointed by the Council of a County or County Borough to be a Venereal Diseases Officer shall be a registered Medical Practitioner, who, prior to the 1st April, 1930, has held the appointment of Venereal Diseases Officer with the approval of the Minister, or who (1) has had at least three years' experience in the practice of his profession subsequent to qualification, and (2) is in possession of a certificate, given by the Venereal Diseases Officer of a treatment centre at which not less than 500 patients attended for the first time during the 12 months preceding the issue of the certificate, *testifying that he has attended* at the treatment centre for a period of not less than three months and has received during that period not less than 130 hours' instruction in the modern methods of diagnosis and treatment of venereal diseases."
3. The holding of a Diploma in Public Health, and practical experience in Bacteriological laboratory work will be deemed additional qualifications for the post.
4. He will act under the directions of the County Medical Officer, and will be required to reside in the City of Durham or other approved centre.
5. He will be required to give instruction in modern methods of diagnosis and treatment to general practitioners attending the clinics.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination, as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, endorsed "Venereal Diseases Medical Officer," together with copies of not more than three recent testimonials, must be received by the County Medical Officer, Shire Hall, Durham, not later than the 29th instant.

Shire Hall, Durham. HAROLD JEVONS, Clerk of the County Council

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A RESIDENT MEDICAL OFFICER is required at the COUNTRY BRANCH HOSPITAL, Tadworth Court, Tadworth, Surrey, on April 28th.

Gentlemen are invited to send in their applications to the Secretary, before 12 o'clock on Monday, March 31st, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for six months, but the successful candidate will be eligible for re-appointment.

Salary at the rate of £250 per annum, with board-residence in the Hospital, laundry allowance at the rate of £10 per annum, and, on re-election for a further period of six months, £18 18s. for the purpose of providing a substitute during annual leave of a maximum of four weeks.

Candidates must possess a legal qualification to practise, and must have held a responsible resident appointment at a General Hospital.

All candidates must be in attendance on Wednesday, April 2nd, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
March, 1930. Secretary.

Hospital of St. Cross, Rugby.
(114 Beds.)

Applications are invited for the posts of SENIOR and JUNIOR RESIDENT MEDICAL OFFICERS (males).

Candidates must be registered Medical Practitioners, and must be prepared to begin duties on May 1st. Salary for the Senior post at the rate of £150 per year, Junior at the rate of £100 per year, with board and residence in the Hospital.

Candidates are requested to state whether they are prepared to accept the post of Junior if not selected for the Senior office.

The appointments are for a period of six months only; at the end of that time the Junior will be eligible to apply for the Senior post, which then becomes vacant.

This Hospital is recognized by the University of London for the purpose of the M.D. and M.S.

Applications, stating age and qualifications, with copies of three recent testimonials, should be sent to me by Wednesday, March 26th.

W. COCKBURN, Supt. & Secretary.

(*b*) HOUSE SURGEON. Vacant May 1st.

The Board of Management invites applications from suitably qualified male candidates for appointment as (*a*) House Physician, (*b*) House Surgeon. It is desirable that the House Surgeon shall be experienced in Obstetrics.

An honorarium of £125 per annum will be paid in respect of each appointment, which will be for a period of six months as from (*a*) House Physician, April 1st, and (*b*) House Surgeon, May 1st.

Applications, accompanied by copies of not more than three recent testimonials, should be sent to the undersigned to reach him not later than 10 a.m. on Monday, March 24th, for the House Physician, and 10 a.m. on Friday, April 4th, for the House Surgeon.

EDWIN RADFORD,
Secretary-Superintendent.

Shropshire Orthopædic Hospital
AND AGNES HUNT SURGICAL HOME,
OSWESTRY.

Two HOUSE SURGEONS (male) required in April. Appointment for six months, with possibility of extension. Salary at the rate of £200 per annum, with board, residence, and laundry. Two weeks' holiday for each six months' service.

Applications, stating age, with copies of three recent testimonials, should be received by the Secretary Superintendent on or before March 31st.

The London Lock Hospitals,
91, Dean Street, W., and
283, Harrow Road, W.9.

The Board of Management invite applications for the following appointments:

(1) SURGICAL REGISTRAR to the Male Lock Hospital, and
(2) SURGICAL REGISTRAR to the Female Lock Hospital.

Honorarium in each case £100 per annum. The appointments are for one year. Candidates, who must be doubly qualified and duly registered, are invited to send in their applications, together with three copies of testimonials only, to the Secretary at 283, Harrow Road, W.9, not later than 10 a.m. on March 24th. Copies of the Laws and By-laws relating to these appointments can be obtained on application to the Secretary. Candidates must be Fellows (or Members) of the R.C.S. England, or Surgical Graduates of a University of the United Kingdom.

By Order of the Board,
HY. J. EASON,
March 6th, 1930. Secretary.

The London Lock Hospital,
91, Dean Street, W.

The Board of Management invite applications for the post of FIRST HOUSE SURGEON and SECOND HOUSE SURGEON at the Male Lock Hospital. Candidates must be doubly qualified and duly registered. The salary attached to both appointments is at the rate of £200 per annum, with furnished rooms, full board, and laundry. The appointments are for six months. Duties to commence April 5th. Applications, enclosing copies (only) of three recent testimonials, to be sent to the undersigned at the Male Lock Hospital, 91, Dean Street, W., on or before March 24th.

By Order of the Board,
HY. J. EASON,
March 6th, 1930. Secretary.

Metropolitan Hospital,

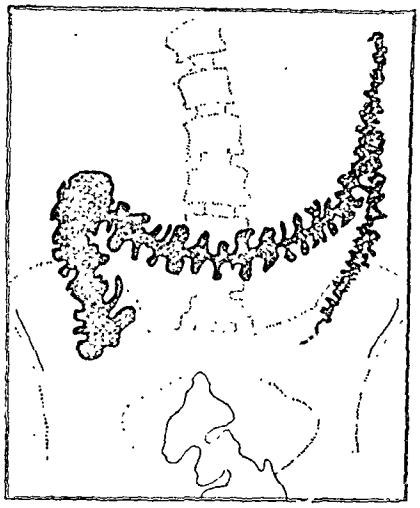
IT OR MORNING?—WHEN TO TAKE LAXATIVES

re can, of course, be no universal rule as to taking of laxatives. Circumstances vary, and ly the physician is in a position to judge their levance. But experience seems to show that a ood deal of harm is often done by the common abit, continued over long periods, of taking aperients at bed-time. At night, the colon is *normally* much less active than in the day; and it seems unwise, unless special reasons exist, to stir it to unwonted activity during the hours which should be allotted to sleep. It is probable that much insomnia and many rest-disturbing dreams have their origin in the taking of a nightly purgative.

When there is an habitual tendency even to slight constipation, not fully remedied by diet and exercise, it is suggested that the most satisfactory result can generally be obtained by the taking, first thing in the morning, on an empty stomach, of a simple refreshing saline draught, such as Eno's "Fruit Salt" provides. Eno is a saline effervescent of fine granular consistency, containing no trace of irritating mineral salts, such as Epsom and Glauber. Owing to its purity and texture, it is agreeable to the palate, its pleasantness owing nothing to added sugar or flavouring matter, from both of which it is entirely free.



"The Doctor's Emergency Reminder."

The Proprietors of ENO's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

J. C. Eno Ltd., 160, Piccadilly, London, W.1.

ENO'S "FRUIT SALT"

Occult Constipation

Occult constipation (from an X-Ray) 24 hours after opaque barium meal. There has been one small stool as usual. Note the deep haustrations and partial dilatation of the cæcum.

THE menace of occult constipation lies in the fact that the patient may have regular daily evacuations, and is therefore unaware of the constant retention of fæcal matter, which may ultimately form a hard and deep coating on the intestinal wall, leaving but a small passage through which painful and partial evacuation takes place.

When headaches, lassitude, and the conditions usually associated with the development of intestinal toxæmia lead to the suspicion of hidden constipation, the reliance of many physicians is on AGAROL Brand Compound, *the original mineral oil and agar-agar emulsion.* Combining lubrication with softening of the fæcal mass and gentle peristaltic stimulation, AGAROL Brand Compound is particularly indicated in cases of occult constipation — because of its positive, yet gentle action, without habit formation.

AGAROL Brand Compound is the *original* Mineral Oil–Agar-Agar Emulsion and has these special advantages:

Perfectly homogenized and stable: pleasant taste without artificial flavouring; freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

A generous trial quantity sent on request

AUTHORITATIVE

Graham's Surgical Diagnosis

Graham's *Surgical Diagnosis* is diagnosis in detail. It is the thorough presentation of every aspect—history-taking, examination of the patient, symptoms, complications, atypical as well as typical cases—all making for completeness and accuracy.

By a painstaking discussion of differential diagnosis, misleading signs and symptoms are explained and the many clinical presentations of a disease or condition are set out in sharp outline. Indeed, this clinical tone is immediately perceived upon opening the work, and springs from the practical experience of the authors.

Bedside and laboratory methods are described, the guiding idea throughout being to help you make your diagnoses more accurate, less presumptive. But Dr. Graham does not stop here; he includes full consideration of the diagnosis of post-operative complications—those dangerous sequelae which are frequently dismissed briefly in the usual book on surgery. There are 1,275 illustrations.

Three octavo volumes totalling 2,751 pages, with 1,275 illustrations and a separate Desk Index Volume. Edited by EVARTS A. GRAHAM, M.D., Bixby Professor of Surgery, Washington University, St. Louis. Per set: Cloth, 15½s. net

CHRISTOPHER: MINOR SURGERY

"THE HOUSE SURGEON WILL FIND IT INVALUABLE"

"This is a very good book. Its arrangement follows the usual lines except for the welcome addition of a long chapter designed for 'The Surgical Intern.' This is full of sound advice which may be read with profit, not only by the house surgeon, but also by his chief, and is mostly applicable to residents in our own hospitals. . . . The book is admirably printed on excellent paper and the illustrations are superb. The consulting surgeon and the practitioner will find much to interest them, while the house surgeon will find it invaluable."—THE LANCET.

By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery, Northwestern University Medical School, Chicago. With a foreword by ALLEN B. KANAVEL, M.D., F.A.C.S., Professor of Surgery, Northwestern University Medical School. Octavo of 691 pages, with over 600 illustrations on 465 figures. Cloth, 36s net.

GRANGER: PHYSICAL THERAPEUTIC TECHNIC

"PLENTIFULLY INTERSPERSED WITH PRACTICAL HINTS"

"The whole book is plentifully interspersed with practical hints on technique, helpful both to the beginner and to the specialist who has developed his own technique, but who is always open to improvements or suggestions."—JOURNAL OF THE MEDICAL ASSOCIATION OF SOUTH AFRICA (B.M.A.).

By FRANK B. GRANGER, A.B., M.D., Late Physician-in-Chief, Department of Physical Therapeutics, Boston City Hospital. Octavo of 417 pages, with 135 illustrations. Cloth, 30s net.

W. B. SAUNDERS COMPANY LTD. **9, Henrietta Street** **LONDON, W.C.2**

The Complete Set of Three Volumes (value £7 7s.), when ordered together, for £6 13s.; carriage 2s.; or separately as below.

With 130 Illustrations (some in colour). Sup. Roy. 8vo. 722 pp. Bevelled Boards.
£2 2s. net. Postage 1s.

Here's the 10/30

—the Car you've been waiting for.

Here's a new Fiat, entirely new in conception and design, but with the same amazing reliability which marked the famous 10/15. Thousands of British motorists know there never was a car which stood up to its job so well over years of hard running. To them, the heir to such a tradition needs no further recommendation.

Yet this new 10/30 marks as great a step forward as did its famous predecessor. It has a range of power, of speed, of complete accessibility such as only the most modern of engineering skill could provide. Even Fiat have never offered quite such value for money in every detail as this handsome 4-door Saloon at £260 complete.

Study these details of the 10/30. Compare it with any other car at the price.

A silent and flexible four-cylinder engine, with only a £12 tax, not dependent on revolutions for power, resulting in length of life and freedom from repairs but giving amazing acceleration and speed. Close ratio 4-speed gearbox, really silent in action, exceptionally easy change. Powerful brakes, in keeping with the engine potentialities, rod operated on all four wheels. A finish comparable with the most expensive cars and containing all the fine points of the higher power models. Coachwork possessing both comfort and enchanting appearance. Chromium plating throughout.

Before you decide on any other car, see this new 10/30. Examine it. Test it. Try it on the road. Send the form below for Catalogue M.9 now and judge its value for yourself.

The Treatment of Pulmonary Affections by Inhalation.

THE AËRISER

This instrument converts liquids into a voluminous but almost invisible vapour, or, in the words of the "LANCET," it "renders fluids like smoke," and thus enables medicated vapours to be inhaled continuously without injury to the delicate mucous lining of the air passages.

In all other sprays, atomisers, inhalers, etc., the spray is given off in palpable particles and cannot be used long without giving rise to discomfort. With the Aëriser, however, solutions, whether aqueous, oily, or balsamic, are given off in such a state of fine division that when the vapour is directed on to a sheet of glass or paper it remains unsoiled; consequently, when inhaled the medicament reaches the whole of the respiratory tract even to the innermost recesses of the lungs without causing the slightest irritation.

A COMPACT, YET PRACTICAL X-RAY OUTFIT FOR THE DOCTOR'S SURGERY

Victor Stabilized Mobile X-Ray Unit.

Here is an outfit which has solved the problem for many doctors who desire compactness as one of the first requisites in an X-Ray outfit, without any sacrifice in the quality of radiographs produced, and combining simplicity and convenience in operation.

The Victor Stabilized Mobile X-Ray Unit is a complete, self-contained unit incorporating the Victor-Kearsley Stabilizer —**an exclusive Victor feature**—which standardizes technique and insures good radiographs consistently. This Stabilizer is one of the most important X-Ray developments in the last decade, having made possible the wider use of X-Rays by doctors through greatly simplified control and uniform results.

Note the large rubber-tyred castors which make it a truly mobile outfit, easily shifted around the room.

Hospitals, too, are supplementing their stationary X-Ray equipment with this Mobile Unit, finding it ideal for bedside work in cases where the patient cannot be conveniently moved to the X-Ray room

What are your X-Ray requirements? We can help you meet them in the most practical way.

WM. GAYMER & SON, LTD., ATTLEBOROUGH, NORFOLK

"The effect on the bowels has always been most marked"

The effect of a deficiency of Vitamin B upon the human system is not always observed, because it shows only as General Debility, Digestive Derangement, etc., for which other causes may have been assigned.

But when the deficiency is remedied by the addition of BEMAX the definite improvements recorded leave no doubt as to the cause of the indisposition.

The restoration of digestive health, the improvement in physical and nervous tone, are seen within a few days.

BEMAX is a natural tonic vitamin food prepared from the living embryo of selected cereals. It contains a higher proportion of natural Vitamin B than any other known substance, together with Vitamin A and E and valuable mineral salts.

Laboratory reports on BEMAX and a sample tin for personal trial will be sent to any medical man on receipt of his professional card.

C.O. 72.—I have prescribed it many times and the effect on the bowels has been the most marked feature.
—, M.B.

C.O. 86.—In a few days the child seemed full of energy.
—, L.R.C.P.

C.O. 132.—Marked improvement in health in about a fortnight. Constipation benefited.
—, M.D.

D. 5.—Immediately invigorates. It is very sustaining. I am sure it did me good.
—, L.R.C.P., L.R.C.S.

Intestinal Disinfection

ALIMENTARY TOXÆMIAS

PUTREFACTIVE bacteria increase in numbers in the intestine as age advances. They are relatively scanty in the young child, but after middle life are usually present in considerable numbers Of the micro-organisms concerned, proteolytic anærobes are probably the most important.

In individuals with a normal intestine and free evacuations, they may do little harm, but in those subject to intestinal catarrh, these putrefactive bacteria become more numerous and active, their products are formed in greater quantity and are more freely absorbed, and the condition of alimentary toxæmia results. The manifestations of this state are very protean, *e.g.*, "rheumatic" conditions, digestive upset, neurasthenia and neuralgias, increased blood pressure and its complications, and many others. The treatment, in the first place, obviously should be *intestinal disinfection*. For this purpose nothing surpasses the use of KEROL CAPSULES. They have solved for years the question of disinfection of the alimentary tract. They definitely reduce the bacterial content of the intestine, as shown by the reduction in *B. coli* by 99% when the capsules are regularly administered for a period of from seven to ten days.

We have from time to time published several booklets containing clinical evidence as to their value, and these we will gladly forward, on receipt of a postcard, to any member of the Medical Profession.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

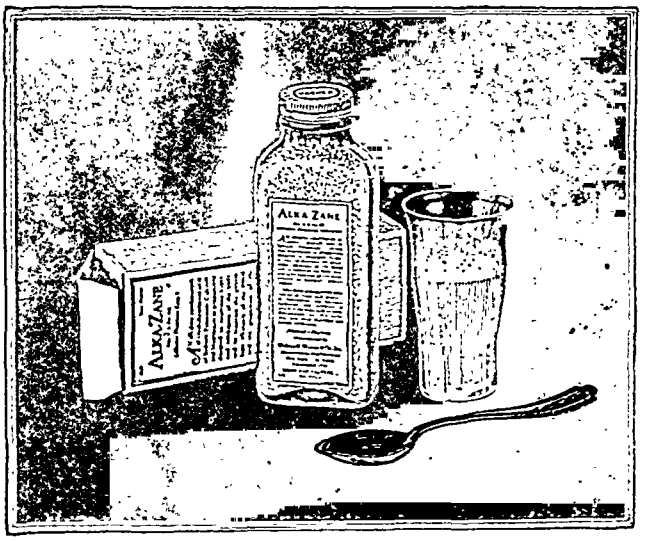
TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.



Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

When the buffer bodies are depleted

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

as in acidosis, acidemia and their correlated pathological disturbances, rational alkaline medication is essential.

Alka-Zane containing alkaline salts in proportions adapted to the physiological requirements of the body, promptly corrects hyperacidity, promotes diuresis and the restoration of the all-important alkaline reserve.

A trial will demonstrate the outstanding merits of

ALKA-ZANE

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

RADIO-MALT

The Ideal Spring Tonic

The lack of tone and general run-down conditions prevalent in the spring were at one time attributed to the effects of changeable weather; they are now generally recognised as being due to lack of resistance following the demands made on the reserve during the winter months.

Recurrent attacks of the common cold and other catarrhal conditions render the individual all the more liable to further attacks in consequence of the depletion of the body-stores of vitamins. What is indicated is a restorative tonic which will build up resistance and clear away the aftermath of winter.

Radio-Malt, on account of its properly-controlled content of Vitamins A, B (B_1 and B_2) and D, exerts a remarkably beneficial effect, restoring waste tissue, building up resistance against infection, stimulating the appetite and assisting in the better assimilation of food.

Radio-Malt, therefore, is the ideal tonic to be prescribed for general family use during the spring season.

LIVER EXTRACT B.D.H.

In Pernicious Anæmia

In the treatment of pernicious anæmia it is important to differentiate between those products which have proved to be efficient as a result of exhaustive clinical trial and those which are still in their experimental stages.

Liver Extract B.D.H. is a product of proven value; clinical experience covering a long period in hospital and in general practice have confirmed the findings of the earlier workers that Liver Extract B.D.H. is a valuable therapeutic agent in the treatment of pernicious anæmia and that the maximum clinical effects are uniformly produced when this product is administered.

The hæmatopoietic principles in Liver Extract B.D.H. which have proved useful in the treatment of pernicious anæmia are now being employed in the secondary anæmias.

Liver Extract B.D.H. is made under scientifically-controlled conditions by a process tested and found efficient by the Medical Research Council. It is a palatable powder, simple in use and not distasteful even to invalids.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

THESE ESSENCES PROVIDE RAPID STIMULATION AND RESTORE VITALITY . . .

•

WHEN SOLID DIET IS OUT OF THE QUESTION

A RECENT investigation showed that out of *every* 100 *doctors interviewed* 99 are recommending Brand's Essences for their patients.

These Essences can be swallowed without effort and rapidly absorbed by the digestive organs for they consist only of the pure essences of the finest meat conserved in natural jelly form. No substances are added — such as colouring matter, gelatine or preservatives, which could hinder assimilation.

Containing those properties of meat which excite the gastric secretions, Brand's Essences stimulate the digestive organs to instant activity. When illness leaves the patient in an exhausted condition, they restore vitality rapidly, and in convalescence they help to overcome the patient's intolerance of solid food by rousing the appetite.

Brand's Essences can be obtained at chemists and stores throughout the world in tins and glasses. On receipt of a professional card, samples will be sent to you immediately. Write Dept. F1, Brand & Co. Ltd., Mayfair Works, Vauxhall, S.W.8.

OUT OF EVERY 100 DOCTORS RECENTLY INTERVIEWED 99 RECOMMEND

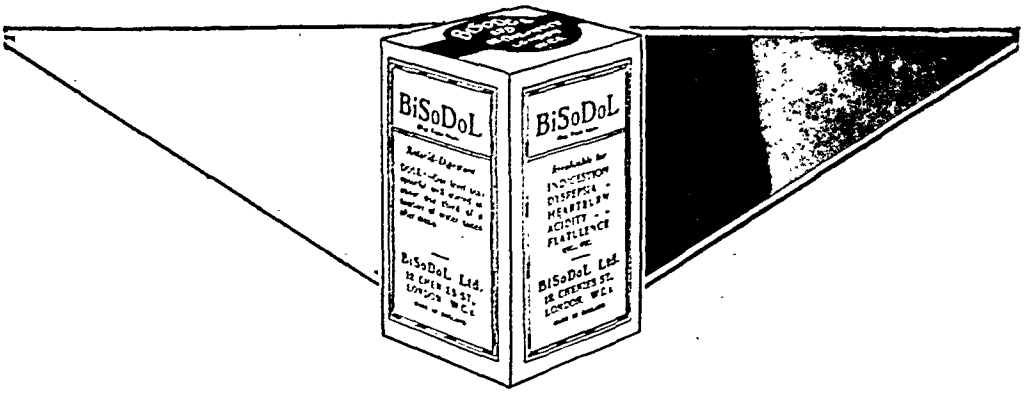
BRAND'S ESSENCES

MADE ONLY FROM THE FINEST ENGLISH BEEF, CHICKEN AND MUTTON

WHY K-Y JELLY FOR CATHETER CASES?

K-Y Jelly reduces the discomfort of instrument-introduction and manual examination more efficiently than any similar lubricant. It is more "slippery" than petrolatum, flows easily, and never binds. It is emollient and antiseptic and does not interfere with the application of local remedies.

K-Y Jelly is prepared from certain vegetable substances blended in correctly balanced proportions with boric acid, and never spoils or becomes rancid or odorous.



Physicians and Surgeons are invited to write for samples to *Dept. B*, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating the name of their local supply house.

* * *

K-Y Lubricating Jelly is obtainable from medical supply houses and pharmacists throughout the world. Tubes in cartons, 1/3 (*Hospital size,* 2/6).

K-Y JELLY IS A MORE EFFICIENT LUBRICANT . . .

JOHNSON & JOHNSON (GT. BRITAIN) LIMITED, SLOUGH AND LONDON

An Effective Antacid and Digestant

The Physician is constantly called upon to prescribe for digestive disturbances. In the treatment of such cases, BiSoDoL will be found a reliable preparation.

BiSoDoL is a balanced formula presenting in suitable proportions the bases Sodium and Magnesium, with Bismuth Subnitrate, Carica Papaya, Malt Diastase and Mentha Piperita.

BiSoDoL is agreeable to the Patient and no unpleasant symptoms follow its administration.

BiSoDoL is quickly effective. Beneficial results have been especially marked in cases of impaired digestion, and in the control of cyclic vomiting, and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,
12, Chenies Street, London, W.C. 1.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & CO. LTD.

ETHYL CHLORIDE

CHLORYL ANÆSTHETIC
(DUNCAN)

FOR GENERAL and LOCAL ANÆSTHESIA
IT IS INDISPENSABLE IN THE SURGERY

Duncan

Ethyl Chloride (Duncan) is perfectly free from hydrochloric acid, empyreumatic bodies, etc. It has a pleasant ethereal odour and its vapour is non-irritating.

Descriptive Booklet and Prices on Application

Supplied in 60 c.c. graduated flasks or in 5 c.c. hermetically sealed ampoules.

May be had perfumed with Eau de Cologne if desired.

DUNCAN, FLOCKHART & CO.

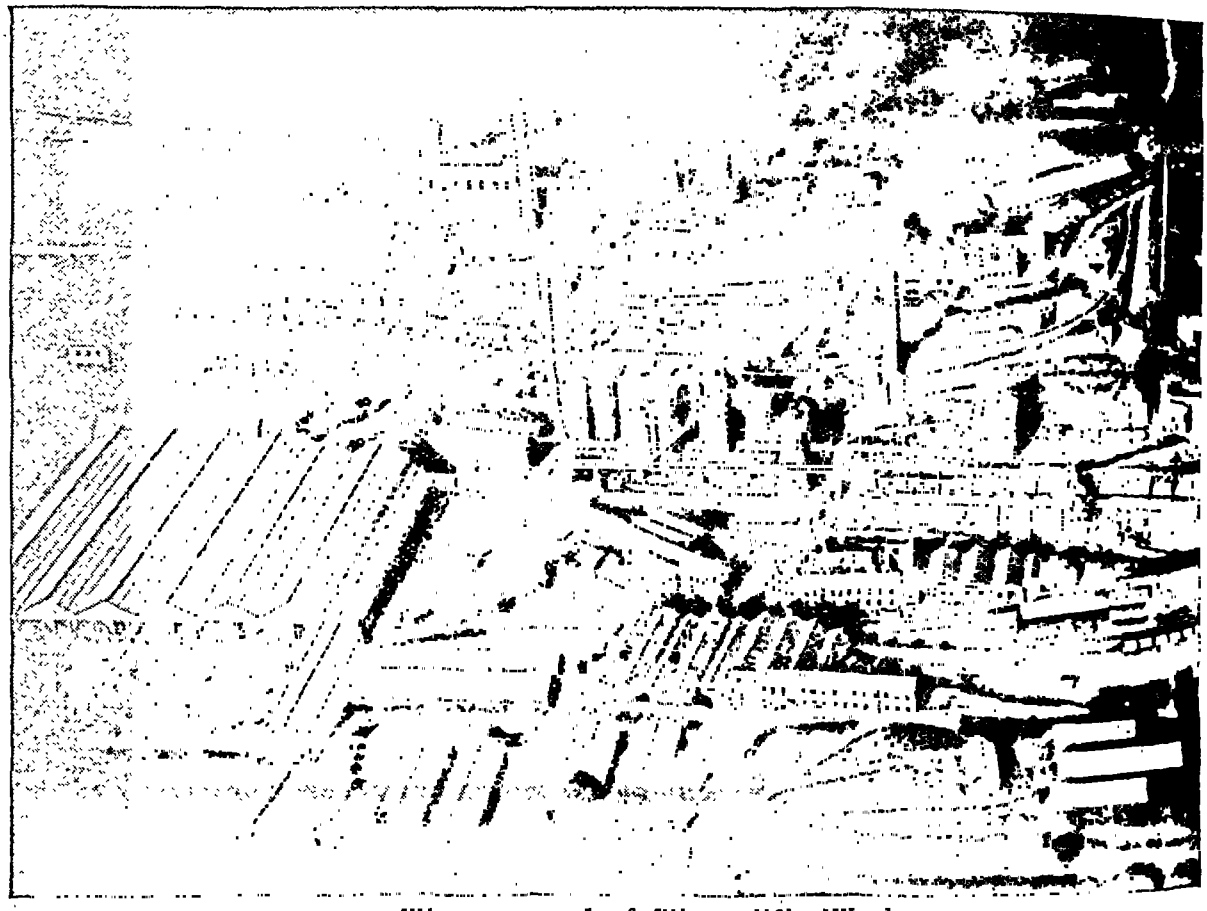
PLURIGLANDULAR DISPENSING

The choice of pluriglandular formulæ for the various conditions in which organo-therapy is indicated is often difficult. There may be a considerable difference of opinion as to dosage, and physicians may from their practical experience decide something quite definite but which is probably not in accordance with the usual formulæ.

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland substances is always in stock and prescriptions can be promptly and accurately dispensed.

THYROSEX CO.



This is one of our recognised formulæ. It is put up in Tablets and in Elixir form, each dose representing Thyroid sicc gr. $\frac{1}{4}$, whole Ovary sicc gr. $\frac{1}{2}$, whole Pituitary sicc gr. $\frac{1}{10}$. It is designed for the treatment of the sexual disorders of puberty and for the neuroses and psychoses of menstruation. Full particulars of this and other formulæ will be found in our brochure "PLURIGLANDULAR FUNCTION" which may be had on application to

Evans Biological Institute, Runcorn.

There Can Be Only One GENUINE Original

In this country the original German "Lysol" is called MARSHALL'S LYSOL.

The name MARSHALL'S has been added to distinguish the original product for **your protection.**

Before the War MARSHALL'S was the only Lysol made, and it has forty years' experience behind it.

Marshall's Lysol is Guaranteed

To contain 50% purest Cresylic Acid especially manufactured to our own specification.

To have a Rideal-Walker coefficient of 2.58.

To be entirely free from alkalinity.

To contain no Phenol.

To be non-caustic in action.

To be stable and uniform.

You can only be certain of obtaining the genuine original by specifying and insisting upon

MARSHALL'S
GENUINE ORIGINAL
LYSOL

It is important to stress the name "MARSHALL'S."

NATURALLY RICH IN VITAMIN "D"

DEMINERALISED PASTURES

The nutritional value of a milk is intimately dependent on the diet of the cow. Any deficiencies in the diet are reflected in the quality of the milk.

It is now universally acknowledged that of the various factors of nutrition, mineral salts play the most important role. Lime and phosphate deficiencies, which are widely prevalent in many milk producing countries, result in milks poor in these minerals, and in gradual deterioration of the stock which has to be made good by the constant influx of new blood from the herds of this country.

The importance of ample supplies of these essential mineral salts in a milk used for infant feeding requires no stressing. It is futile for a milk to be rich in Vitamin 'D,' whether naturally so or as a result of additions in the shape of irradiated ergosterol, unless the calcium content is adequate.

Milk used in the preparation of Cow & Gate is produced from the rich pastures of Somerset and Dorset where cattle are healthy and sturdy, and have never displayed those symptoms of mineral deficiency which result in "osteophagia" or wanderings to "salt licks" so often met with overseas.

The improved Cow & Gate Roller process carried out in modern hygienic factories, ensures the retention of the calcium and phosphorus salts of the original milk and preserves the balance of natural vitamins required for their assimilation by the infant. For this reason it is unnecessary to add synthetic Vitamin 'D' to Cow & Gate products.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

In Convalescence

after Influenza, Pleurisy, Pneumonia, Bronchitis.

The soothing, inflammation-allaying properties of Angier's Emulsion and its general tonic effects especially commend its use in convalescence from acute respiratory affections. It will clear up any remaining catarrh, whether of the respiratory or digestive organs. It will restore tone to the digestive functions, and greatly improve assimilation and nutrition.

An absolutely perfect emulsion, it is presented in a form pleasing to the taste, and acceptable to the most fastidious. Moreover, it can be administered to advantage in conjunction with other remedies, such as salol, aspirin, bismuth, etc.

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original petroleum emulsion — the result of many years of careful research and experiment.

TOWER BUILT BY THE BYZANTINES TO GUARD THE HARBOUR OF CONSTANTINOPLE.—During the thousand years when Byzantium acted not only as the bulwark of civilisation for the whole world, but herself initiated new developments, hardly a century passed during which she was not assailed by Asiatic hordes. Nevertheless, upon certain of her conquered foes who were capable of receiving it, she impressed her civilisation; thus, for example, she took the first steps towards making the Serbs, Croats, Bulgars and Russians, European nations, giving them religion, architecture, influencing their literature, teaching them commerce and to respect treaties. The tower here reproduced was one of those designed to guard the harbour of Constantinople, where the largest fleets could find anchorage and the busy trading ships brought wealth. Within the walls was preserved the secret of the "Greek Fire" invented by the Byzantine Greeks and used in the many sieges to which their capital was subjected through the ages. Two names are associated with the construction of the harbour of which this tower forms a part—Eleutherius and Theodosius I, who helped to build up the great power which arose at this, one of the most important land and sea highways of the world.

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

The Association's Report, dated June, 1929, states that the Iron as ferrous sulphate occurs in these samples in proportions varying from 170 to 1,275 grains per gallon, combined with Aluminium Sulphate and free Sulphuric Acid.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 2 grains of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures —

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable.

Close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W.1.

An Address
ON
CHRONIC INFECTION OF THE CERVIX:
A FREQUENT CAUSE OF PELVIC AND GENERAL ILLNESS.

BY
JAMES YOUNG, M.D., F.R.C.S.,
GYNAECOLOGIST, ROYAL INFIRMARY, EDINBURGH; PHYSICIAN, ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.

The past few years have witnessed three advances in the practice of gynaecology, each significant in the measure in which it has led to a saving of life or the alleviation of pain and illness. The first of these has been the establishment of the palliative as opposed to the operative treatment of all but the exceptional cases of active salpingitis. In the past it was customary to carry out surgical intervention, ending often in extensive and mutilating operations and attended with a not inappreciable mortality, in those cases deemed to be streptococcal, the palliative procedure being reserved for the gonococcal cases. The rapid immediate recovery which is now known to follow the same regime of non-operative expectancy in both types of case has removed from the practice of the gynaecologist one of his greatest responsibilities in diagnosis, as it has resulted in the saving of lives and in the conserving of organs which the surgeon formerly considered it necessary to sacrifice. The new treatment has further vindicated itself in the frequency with which apparently grossly damaged appendages can exhibit clinical if not functional cure. Immediate abdominal operation is now reserved for those comparatively rare cases where laparotomy is the only method of removing diagnostic confusion with appendicitis and tubal pregnancy, and, on infrequent occasions, a pelvic abscess of tubal origin requires to be drained through the vaginal vault. Where persisting symptoms finally demand active intervention this can now be planned during a quiescent period and after the lapse of an interval during which death of the infective organism can be presumed to have occurred.

The second notable advance springs from the recognition of the frequency of strains of the spinal joints in gynaecological cases. With the help of Mr. W. A. Cochrane we are carrying out a special study of these cases in the gynaecological department of the Edinburgh Royal Infirmary, the results of which will be published in due course. Meanwhile we feel justified in saying that the recognition of this orthopaedic source of many of the low back pains which used to persist after our operations for prolapse, backward uterine displacement, etc., has brought with it a very great accession to the scientific treatment of our patients.

The third noteworthy advance in our subject during recent years is the recognition of the extent of the distress and ill health caused by chronic infection of the cervix. This lesion has long been recognized, and we know that from early times one of the most common therapeutic measures consisted of the local application of caustic drugs to "erosions" of the cervix. The old textbooks bear witness to the frequency of this practice. At the same time, the older attitude did not extend much beyond one which regarded the lesion as a sort of simple ulceration from which unpleasant discharges continually drained away.

It has remained for this generation to grasp more fully the wider clinical significance of the condition, and the object of this paper is to demonstrate that in many cases it is responsible for pelvic and abdominal distress, and that it may play, in addition, a profound part in the production of general ill health. Take the following illustrative cases.

1. A 2-para, aged 31, since the birth of her second child three years ago has suffered from constant leucorrhoea with more or less constant pain in the left iliac fossa. Menstruation has been regular and excessive. The general health has been poor, headaches and attacks of faintness being common. Blood pressure, 150/100.

2. A 6-para, aged 37, for six years has had leucorrhoea with pain in the lower abdomen, exaggerated before and during micturition. There have been bladder irritability and frequency, headaches, rheumatic attacks in wrists, and constant feeling of fatigue.

These instances are selected from a large number of patients in whom chronic cervicitis was present, and in whom treatment directed to this condition resulted either in a complete cure or in a noteworthy alleviation of the clinical features.

Space forbids me to enter adequately into a discussion of causation and pathology. Suffice it to say that the disease is found more commonly in women who have borne children—the percentage proportion of parous women to nulliparae being about 93 to 7 (Fulkerson[1])—and the most usual causal factor is the damage and the consequent infection the cervix is apt to suffer during childbirth or the puerperium. Lacerations and uterine displacements (prolapse and retroflexion) are thus found as a common accompaniment of chronic cervicitis. A proportion of the cases are gonococcal, although only in comparatively few where the condition has persisted for some considerable time (the usual history) can we isolate the gonococcus. The dominant fact in the pathology of the disease is the resistance to the process of natural recovery which in other parts of the body quickly leads to the spontaneous healing of sores of a similar kind. This intractableness arises from the natural crypts and crevices which exist in the cervix and from the racemose structure of the cervical glands, and the tendency for infection, once it has passed into the deeper layers of the cervix, to be locked up in the recesses of these glands. A contributory factor arises from the lesion being placed within a narrow canal in which swelling of the tissues tends to hamper free drainage.

Curtis[2] has directed special attention to this fact of faulty drainage being an essential element in the pathology as it is a salient consideration in regard to treatment. On examination the diseased cervix is found to be commonly increased in size, with a soft, bulky, and rough rim of reddened mucosa encircling the os and covered with a muco-purulent secretion. It is common to find the cervix lacerated, with an opening up of the lower end of the canal and an exposure of the mucous lining of the endocervix. In many instances the blocked endocervical glands become distended with an infected muco-purulent secretion and bulge on the vaginal surface of the cervix as small hard cysts (Nabothian follicles). Radiating from the cervix into the surrounding parametrium we often find bands of tissue, frequently tender to pressure, which are due to cicatricial shortening in cellulitic deposits or to the healed vaginal extension of a cervical laceration. These bands immobilize the cervix and drag it from its central position. An interesting phenomenon is that such bands may sometimes be found to disappear under anaesthesia, proving them in these instances to be due to muscle spasm and not to any organic change in the affected tissue.

CLINICAL FEATURES OF CHRONIC CERVICITIS.

The most constant symptom is leucorrhoea, and this in many instances is the only pelvic complaint, although it is common to find even in such patients evidence of impaired general health. Pain in the pelvis or abdomen is the next most common local symptom. Bladder and menstrual troubles are frequent and the general health may be involved in a variety of ways, fatigue, headache, arthritis, and cardio-vascular disturbances being amongst the most frequent manifestations. Leucorrhoea consists of a more or less persistent vaginal discharge, sometimes thin and watery, more often thick and creamy, and sometimes frankly purulent. It is prone to irritate the genitals and skin surfaces of the vagina, vulva, and thighs.

Pain in Chronic Cervicitis.

The most distressing of the common symptoms of cervicitis is pain, which is felt usually in the lower abdomen and more especially in one or other iliac fossa or in both fossae. On occasion the pain is situated in the flank or in the upper abdomen, whilst not infrequently it is situated low in the back in the sacral or coccygeal regions, and pain in the hip and thigh would seem sometimes to owe its origin to cervical disease. In many patients there

[3512]

*Delivered to the Edinburgh Obstetrical Society on February 12th, 1930.

is discomfort or even acute pain during the action of the bowels. All these aches and pains are prone to exaggeration before and during the menstrual periods and as the result of exertion.

Because of its wide distribution this pain of cervical origin is apt to be a source of confusion in diagnosis. Tubal or ovarian mischief is often erroneously suspected, and in the presence of a uterine displacement the pain may easily be attributed to this, whilst a common source of abdominal confusion arises from the frequent right iliac fossa pain being mistaken for appendicitis. For all these reasons cervical pain merits our most serious attention.

I would say, in the first place, that as the result of a close study of pelvic pain and its underlying pathology over a considerable number of years I have come to the conclusion that, with the possible exception of vaginal prolapse in its varying degrees, the most common gynaecological cause of pain in the lower abdomen and pelvis in women is chronic cervical infection. The recognition of this common relationship is of profound importance, because it has enabled us to bring relief to a considerable proportion of the patients who in former days constituted our failures, and who in many instances spent their lives in a weary passage from doctor to doctor, suffering often futile operations in the process.

The evidence for this faith is twofold. In the first place, thanks to the accessibility of the diseased organ, it is in the majority of cases easy to demonstrate the relationship between the lesion and the pain. In the second place, as we shall see, the treatment of the disease, which is usually comparatively easy, leads in a large proportion of cases to relief.

Let me amplify the first statement. To understand the ease with which the diagnosis of the origin of the pain can be made we have, to begin with, to consider some simple facts in connexion with the ordinary vaginal examination. If the examining fingers are placed on the cervix and this be moved laterally, antero-posteriorly, and upwards, it is found that in health a considerable amplitude of displacement can be obtained in all these directions, and that even at its maximum this displacement is painless. In cases of cervicitis, on the other hand, this mobility is commonly restricted, and in those cases in which pain is present any attempt to displace the cervix at once provokes the symptom in the location in which it has been complained of by the patient, be it in the iliac fossa, the back, or the bowel. On occasion, pain may be elicited by manipulation of the cervix, although such pain does not appear among the symptoms of the case. In many instances the least pressure on the cervix causes severe pain—the type of case in which dyspareunia is apt to be a particularly distressing symptom. In not a few patients in whom nausea is a prominent clinical feature in the history I have, in addition, found a tendency to retch at once provoked by this procedure—an interesting demonstration of the widespread reflex nervous phenomena that may owe their origin to the genitalia. The nausea and vomiting which are common accompaniments of pelvic disease I have on repeated occasions found to be cured after treatment directed to this disease; this result I can recall more particularly as a sequel to operations for vaginal prolapse.

I have drawn attention to the risk of the abdominal pain of cervicitis being related in error to other abdominal or pelvic organs, with the attendant danger of the patient being subjected to futile operation. Here are three examples.

1. Mrs. A., aged 31, 3-para, was examined by a surgeon because of pain, tenderness, and muscle rigidity in the right iliac fossa. Appendicitis was suspected, but before operation the opinion of a gynaecologist was solicited because of a history of leucorrhoea and low abdominal dysmenorrhoea of some years' duration. On vaginal examination cervicitis was discovered with acute exacerbation of the iliac fossa pain on displacing the cervix to the left side. Treatment for cervicitis was instituted.

2. Mrs. B., aged 29, 1-para, in 1926 had an operation for appendicitis without relief of symptoms. In 1927 she had a fixation operation for retroflexion of the uterus, with removal of a cystic right ovary. The symptoms increased in severity, the pain involving the entire area of the lower abdomen and being associated with marked leucorrhoea and bladder irritability. In 1929 cervicitis was recognized and treated, and this was followed by a disappearance of all the symptoms, except some persisting diurnal frequency.

3. Mrs. C., aged 25, 2-para, in 1928 had a plastic operation for vaginal prolapse and an abdominal operation (Gilliam) for replacement of a retroflexed uterus. The symptoms were relieved but the abdominal pain and the leucorrhoea persisted. In 1929 treatment was carried out for chronic infection of the cervix, with immediate cessation of the leucorrhoea and relief of the pain.

This pain reference from the diseased cervix can be demonstrated easily and conclusively in regard to the common iliac fossa or general low abdominal pain, and also in regard to pain in the sacro-coccygeal region and in the lower bowel. It raises interesting questions both in connexion with the innervation of the cervix and the adjacent tissues and in regard to the nerve channels by which the irritant impulses arising in these sites are registered on the body surface in regions remote from their point of origin.

In the present state of our knowledge it is impossible to formulate an accurate anatomical basis for the phenomena. We know that the vaginal cervix is insensitive to ordinary painful stimuli. It can, for example, be grasped with a sharp vulsellum forceps without pain being elicited. On the other hand, it would seem that the low back distribution of the pains of labour is, at least in part, to be explained by the stretching of the cervix during the labour process. In this connexion Dr. Edwin Robertson has recently shown, in a series of observations carried out at the Edinburgh Royal Maternity Hospital, that by stretching the partly dilated cervix with the finger hooked into the cervical canal pain is at once registered in the sacral area, but here alone. These observations provide some basis for the belief that the common sacral pain of cervicitis may be a reference from the cervix itself. In regard to the common low abdominal and iliac fossa pain there is no such evidence, and we must conclude that here we are dealing with stimuli arising in the nerve elements outside the cervix and owing their origin to the irritation spreading into the surrounding tissues from the cervix. That the inflammatory process is a dominating factor is proved by the clinical demonstration that, whereas traction on these structures is painless in health, in the presence of the infective changes they become sensitive to this manipulation.

The cervix, vagina, rectum, and the adjacent structures are known to be supplied by branches from the hypogastric ganglion which is formed by elements passing into the pelvis from the renal and mesenteric plexuses, and through which it is linked up with the dorsal and lumbar spinal nerves. It establishes in the pelvis a connexion with branches passing directly to the ganglion from the second, third, and fourth sacral nerves. In the light of these facts we may explain the somatic registering of the cervical and pericervical stimuli, the common iliac fossa pain, for example, owing its origin to the central connexion between the corresponding visceral sympathetic twigs and the eleventh and twelfth dorsal nerves. Similarly we may formulate an explanation of the high abdominal pain, nausea, etc., experienced by such patients, on the basis of the linking of the abdominal and the pelvic plexuses. Any attempts thus to account for all the phenomena, however, must in the meantime be tentative pending research in this subject, which constitutes an attractive field in which data still remain to be gathered.

Bladder and Bowel Symptoms.

Bladder symptoms are very common in cervicitis, taking the form of frequency and dysuria. In some cases there is definite evidence of infection of the urinary tract with bacilluria and pyuria, and in such cases it is possible to account for the trouble either by predicating a direct spread of the inflammatory process from the cervix to the adjacent bladder or on the basis of a blood stream infection. In many instances, however, the urine is free from any abnormal elements, and it may be that in such the condition is reflexly induced by sympathetic irritation.

Bowel symptoms are less common than bladder disturbances. Constipation is frequent, but this is so often encountered in women that it is impossible to recognize any relevant bearing. Pain on movement of the bowel, however, which is a not infrequent complaint, suggests a

different category, because here the relation-ship can be directly demonstrated by the bowel pain being accurately reproduced by traction on the cervix.

Menstrual Abnormalities.

Disturbances of the menstrual function, usually in the direction of excess or irregularity, are common, and, as we have seen, premenstrual and menstrual aggravation of the pain in abdomen or back is frequently complained of.

The factors underlying the menstrual excess and irregularity so characteristic of this as of other forms of pelvic infection are somewhat obscure. In the present state of our knowledge it would seem that the alteration in the uterine function is more easily to be explained on the basis of ovarian dysfunction than in terms of a purely uterine pathology. In the majority of such cases there is no obvious uterine disease except a varying degree of hyperplasia of the endometrium with proliferation and dilatation of the glands—changes, in other words, which are more probably dependent upon some ovarian aberration. This in its turn may arise in a variety of ways. It may, for example, be due to the general pelvic congestion which accompanies the primary cervical disease, or to an involvement of the ovary in an inflammatory spread from the cervix, or, in the third place, to influences reaching the ovary by way of the sympathetic.

The dependence of the normal ovarian rhythm upon the other endocrinal glands, especially the pituitary, must naturally raise the question as to how far such disturbances of this rhythm may spring from an involvement of the pituitary in a generalized toxaemia induced by the pelvic sepsis. Such a view draws a certain amount of support from the well-authenticated part played by focal sepsis elsewhere in the body in inducing menstrual abnormalities. On the other hand, the very special relationship known to exist between pelvic infection and menstrual excess, etc., tends to align the evidence in favour of a more local origin of the menstrual disturbances of cervicitis. In two cases of this series in which the patients complained of excessive menstrual loss, and in which panhysterectomy was performed, marked ovarian changes were found. In one a large blood cyst of the ovary, and in the other irregular ovulation, as revealed by persisting and cystic follicles, were found. In the latter case, in addition to a deep-seated cervicitis with the most marked development of Nabothian follicles that I have ever seen, there were marked hypertrophic changes in the uterine muscular and mucous walls. It should be stated that in neither case was there any evidence of inflammatory changes in the tubes and ovaries.

A survey of the pathology, taken in conjunction with the clinical features, and more especially the frequency with which treatment directed solely to the cervix is followed by a restoration of the menstrual process, has led me to the conclusion that we may formulate a satisfactory explanation of the phenomena as follows: (1) infection of the cervix, leading to (2) involvement of the ovaries (by sympathetic disturbances or in some other way), leading to (3) the uterine changes associated with menstrual excess. The establishment of such a view would naturally provide us with an explanation of many otherwise obscure uterine haemorrhages and to at least a partial understanding of the so-called "bleeding uterus" or metropathia haemorrhagica.

General Ill Health from Cervicitis: Rheumatism.

It is becoming increasingly appreciated that the cervix constitutes a not infrequent source of systemic disease, and it is probable that the improved general health and sense of well-being that many women experience after treatment is largely attributable to the eradication of a focal source of sepsis. In the same way are to be explained the improvement and sometimes the dramatic arrest of an active and progressive arthritis that may supervene on treatment of this condition. A series of about a dozen such cases which I have had under my care have convinced me that, where unsuccessful attempts to find focal trouble in the teeth, tonsils, nasal sinuses, and bowel have been carried out, the cervix should always be looked upon with suspicion, and any distress there be brought under prompt control. I have referred to this matter in a communication recently published in this *Journal*,[1] and in it I have cited instances of the speedy arrest of progressive articular disease by the ablation of such pelvic foci. Take the following examples which have recently been under my care.

1. A 2-para, aged 32, had joint rheumatism for about a year, with rheumatic fever three months before her present illness. There had been leucorrhoea for some years often with unpleasant odour, otherwise there was no pelvic discomfort. The tonsils had been removed. Various joints, especially the wrists, were swollen, pale, and tender, with restriction of movement, and getting worse. The general health was poor, with shivering and sweats at night; weight 7 st. 6 lb. The uterus was large and retroverted. The cervix was infected, and manipulation evoked pain in the lower abdomen. Active treatment had to be delayed for ten days owing to fever, which on two days rose to 103° F. and was associated with acute exacerbation of the arthritis. Despite the fever, on October 31st, 1929, dilatation and cauterization of the cervix was carried out under avertin anaesthesia. Within four days the fever settled, the joint swelling and tenderness subsided, and she left the nursing home on the tenth day. On January 13th, 1930—that is, about two and a half months later—the general condition was markedly improved and the weight was 8 st. 10 lb. The wrists and other joints were normal in appearance, and there was no pain except occasional twinges in the knees. There was no leucorrhoea, the cervix being clean, with no pain on manipulation.

2. A 3-para, aged 37, had suffered from chronic ill health since childbirth nine years previously. Of the last two years she had spent eighteen months in hospital for valvular heart disease and progressive rheumatoid arthritis, with marked deformity in wrists, elbows, ankles, and knees. Leucorrhoea was discovered on the last occasion in hospital. The cervix was found to be very septic and was amputated. This was followed by rapid improvement in the condition of the joints and in general health.

Such cases teach us a very important lesson, and it is interesting to find experimental corroboration of these clinical results in the work of such investigators as Laura Moench,[2] who, in Rosenow's laboratory at the Mayo Clinic, has produced arthritis in rabbits by the arterial injection of anaerobic streptococci cultured from the cervix of arthritic women.

TREATMENT OF CHRONIC CERVICITIS

As chronic infection of the cervix is a frequent legacy from child-bearing the ideal time for its recognition and treatment is during the post-natal period—that is, before it has succeeded in producing the deep-seated structural changes and the train of local symptoms and general ill health which characterize so many of our cases. One of the strongest arguments in favour of a post-natal examination of every woman at the end of four or six weeks is the opportunity it gives for the detection of this lesion at an early and easily curable phase.

We have seen that the dominating feature of the lesion is its chronicity, and that this in its turn is dependent upon the peculiar structural arrangements in the cervix which tend to a locking up of the inflammatory discharges. This consideration gives the key to the treatment which must be directed to the opening up of the cervical canal and the establishment of tracks in the cervix along which the pent-up infection can drain freely away. For these reasons active surgical measures are essential. Experience has shown that vaginal douching and the application of caustic or antiseptic medicaments, which have often been employed in the past, succeed in effecting at the best nothing more than a superficial temporary cleansing of the vagina, whilst at the worst they not infrequently do harm by damaging the mucous membranes, and in this way aggravating the inflammatory processes already present. Among the other therapeutic measures diathermy, about which some workers have spoken highly, has in my hands proved unsatisfactory.

In cases where the cervix is greatly enlarged and deeply disorganized the best treatment may consist in amputation, although in some such cases, if the more palliative measures presently to be described fail, the better alternative is panhysterectomy. It is remarkable to find how completely a cervix that is extensively infected and enlarged, with perhaps deep lacerations and its entire substance riddled with Nabothian follicles, can recover as the result of measures directed solely to the establishment of free

drainage. In such cases, however, the treatment may require to extend over several months, and as this deliberateness of procedure is not often permissible in the hospital class of patient, in such amputation or hysterectomy may be the only possible initial alternative course to be adopted.

The routine treatment which I practise is as follows. The cervical canal is dilated to the full extent short of tearing of the tissues, and the mucosa and underlying structures of the cervical canal are seared longitudinally with the stout terminal of the electric cautery along its entire length from internal to external os and including at its lower end the "eroded" area on the vaginal surface. Three such strokes of the cautery on the posterior wall, followed by a similar number on the anterior wall, are usually sufficient. The cauterization is attended with some bleeding, and for this reason it is wise to commence behind. If there are any visible Nabothian follicles these are punctured individually and deeply. In every case it is wise to plunge the cautery deeply into the cervical tissue in one or two places, both in front and behind, and also within and outside the cervical canal.

The dilatation of the cervical canal is an important part of the procedure, since it is only in this way that free access for the cautery and the subsequent free escape of the discharges can be obtained. To allow of the dilatation an anaesthetic is necessary. Curettage is usually neither necessary nor advisable. Where there are deep lacerations with ectropion of the endocervix a repair operation should be carried out. In lacerations of a lesser degree this is not necessary, because after the longitudinal cauterization the internal tissues of the cervix tend to cicatrize and shorten in their long axis, with a consequent rolling in of the mucosa. In some cases the cauterization has to be repeated once or twice at monthly intervals. Healing of the wounds is fairly rapid and the patient is allowed to get out of bed in five or six days. There is usually little or no post-operative pain. On the other hand, where pain has been present before the operation, this often disappears rapidly with the subsidence of the cervical infection, and before the patient leaves the hospital or nursing home the pain elicited by manipulation of the cervix has frequently also disappeared.

After-Results.

For this investigation we have a consecutive series of hospital and private cases which have been brought under special study for this purpose during the year 1929. In attempting to assess the value of treatment it has been necessary to select for analysis out of the large number of patients with cervicitis under our care during this period those in whom this was the solitary lesion. This segregation is necessary because in many cases the cervicitis is merely one feature in the total disease picture, the symptom complex being built up of such conditions as retroflexion, vaginal prolapse, salpingitis, etc., in combination with cervicitis, and in which for purposes of accurate analysis it is often impossible to allocate the exact source of the individual subjective phenomena. At the same time I have included in my figures those cases in which, after operations for prolapse, retroflexion, appendicitis, etc., the persistence of symptoms has been considered to be due to the existence of an untreated cervical infection.

After these allowances we are left with a total of 86 successive cases. Of these, 69 were parous and 17 nulliparous women; of the latter, 9 were married and 8 single. The relatively high proportion of nulliparae in this list is doubtless to be explained by the exclusion, for reasons just stated, of a large number of cases in which cervicitis was combined with other lesions, such as displacements, whose incidence is highest in the married.

The results, as judged after an interval varying from two months to twelve months subsequent to the last treatment, are available in 75 out of the total of 86. To increase the accuracy of the findings the two most important symptoms—namely, leucorrhoea and pain, in regard to each of which precise data could be fairly expected—were segregated for purposes of special investigation. It so happens, however, that a large body of valuable evidence has been obtained in regard to some of the other symptom data—for example, the state of the general health, the menstrual and bladder functions—although these cannot be set out with the same statistical precision.

Leucorrhoea.—In 74 cases positive information is available. In 1 there was no leucorrhoea to begin with. In 44 (60 per cent.) there was complete cure, and in 13 (18 per cent.) improvement in this symptom—that is, in 78 per cent. there was cure or improvement. In 16 (22 per cent.) there was no appreciable abatement, in 2 it was stated to be worse.

Pain.—In 75 patients in regard to whom we have information, 8 had no previous pain. There was complete cure of this symptom in 33 out of the remaining 67 (49 per cent.), whilst there was improvement in 21 (31 per cent.). The total cure or improvement percentage is therefore 80. In 13 (20 per cent.) the pain was unaffected by the operation, whilst in 2 it was stated to be worse.

Menstrual Function.—No special follow-up investigation has been directed to this subject. This is now recognized to have been somewhat unfortunate because the number (20) in regard to whom there is stated to have been a cure of menstrual irregularity or excess, usually both, is so large as to indicate a positive benefit in these respects from the operation. In 5 the condition is put down as unimproved, whilst in 1 there *is stated to have been persisting haemorrhage with only* short dry intervals since the operation four months previously.

Bladder Function.—Although no complete follow-up has been instituted in regard to this condition, in many cure or improvement of frequency or dysuria, or both, is recorded.

General Health.—Marked improvement in general health is the rule in those cases where the other symptoms show abatement. This expresses itself in an increased sense of general well-being, in a loss of such sensations as fatigue, faintness, nausea, etc. These results follow naturally from the cessation of pain and depleting vaginal discharges, to which the removal of a septic focus of toxaemia probably in part also contributes. I have already referred to the significance of this last factor being specially exemplified in those cases in which a progressive rheumatism exhibits a rapid abatement after treatment of the cervix. Two such cases in this series show this well. In one an acute articular rheumatism subsided rapidly after cauterization of the cervix, whilst in another a progressive rheumatoid condition showed signs of arrest after hysterectomy where cauterization had previously failed. This case is especially interesting because a cardiac lesion with commencing decompensation and an associated hypertension both improved markedly after the operation. After an interval of two months the blood pressure had decreased from 200/110 to 140/98, the previous shortness of breath and attacks of faintness and oedema of the ankles had disappeared, and there was a marked general gain in health.

It will be noted that "cure" in terms of leucorrhoea and pain was obtained in 50 to 60 per cent. of the cases. In this connexion it is important to point out that in the great majority of the cases (69 out of 75) the treatment did not extend beyond one application of the cautery, whilst experience shows that in many instances one or two repeat operations are required before the maximum benefit is obtained. This is well seen in the fact that out of 6 patients, who had such recauterization, 5 were "cured." Amongst the 40 to 50 per cent. "uncured" cases it may therefore safely be presumed that a considerable proportion are capable of being further benefited, and that this has not been accomplished is due to a variety of factors, the chief being, on the one hand, the recovery of the cases, and, on the other, the failure of the patients to report at the clinic, and the fact of their condition being discovered only in response to a circular letter requesting them to attend for the purpose of this analysis.

In the series panhysterectomy was carried out on 5 occasions, in 3 by the abdominal and in 2 by the vaginal route. In 2 cases there was cure of the symptoms, in 1 there was marked improvement both locally and generally, whilst in 2 both leucorrhoea and pain persisted and the general health was not appreciably altered.

This question of the persistence of pain in the abdomen and pelvis after the removal of the apparent pelvic source of the trouble constitutes one of the most acute and at the same time most baffling concerns of the surgeon. In some cases it persists after the cervical disease has cleared up, and in such it can only be explained by a perpetuation of the irritation of the sympathetic fibres. In others—as in the two cases I have cited, in which the vaginal discharge and pain persisted after hysterectomy—it is

probably dependent upon a locking up of the sepsis in some of the cellular tissue planes of the pelvis. Cotte[5] of Lyons has claimed to obtain marked relief of pelvic and abdominal pain in otherwise intractable cases from a division of the main trunks of the pelvic sympathetic where they lie in front of the fifth lumbar vertebra, and it may be that with the aid of this procedure we might bring help to some of the distressing cases I have cited. This sympathectomy as described by Cotte I have carried out in one case. It is simple and apparently has no untoward effects on function, and it is therefore specially worthy of consideration in those cases in which it has been decided in any event to open the abdomen—as, for example, for the performance of hysterectomy.

TRAUMATIC AND OTHER AFFECTIONS OF THE KNEE-JOINT.

BY

H. A. T. FAIRBANK, *D.S.O.*, M.S., F.R.C.S.,
SENIOR ORTHOPAEDIC SURGEON, KING'S COLLEGE HOSPITAL.

THE knee-joint is more frequently damaged than any other joint in the body. Let us first consider simple uncomplicated traumatic synovitis of the joint, without a lesion of any important named structure. Such synovitis results from simple strains, blows, and kicks on the knee. The synovial membrane and capsule are slightly damaged by a tear or bruise, the site being indicated, perhaps, by local tenderness and pain. A small amount of blood is effused into the joint, but this is soon mixed with an excess of synovial fluid. The history, carefully inquired into, reveals nothing suggestive of a cartilage or other lesion, while the radiogram is negative. Routine examination shows that the joint can be fully extended. It is as well, perhaps, to emphasize the fact that the treatment demanded by this simple type of case must also form a part of the treatment of all forms of traumatic synovitis. Injuries of special structures call for special methods of treatment, and sometimes for postponement of those to be now discussed, but sooner or later these must be adopted before the joint can be restored to its full function.

Every synovitis is associated with two complications—weakness and wasting of the muscles, particularly of the quadriceps group, and a tendency to the formation of adhesions if preventive measures are not adopted. The objects of treatment are three: to get rid of the excess of fluid in the joint, to restore the muscles to their normal condition, and to obtain full movement, including rotation. These objects are best served by commencing active treatment at the earliest possible moment—that is, within twenty-four hours in an average case. This treatment consists of firm elastic pressure about the knee, massage to the knee and thigh, and faradic treatment of the anterior thigh group of muscles. The last is gradually replaced by active exercises. The pressure is best obtained by covering the knee with a thick layer of wool and a firm bandage. A special pad of wool or felt should be placed over the damaged portion of the capsule or ligament. The massage must be skilfully performed, soothing and not painful, and therefore must be gentle to begin with. The faradic treatment has certain great advantages: it can be used at once when the muscles are still suffering from a functional paresis almost amounting to paralysis. It can be graduated so as to cause contraction of the various muscles without at first producing movements of the joint, and it can be applied to every muscle in the group so that none be allowed to slack. The tensor fasciae femoris and the vastus internus should receive special attention. The importance of the muscles in maintaining the stability of the joint and keeping it free from excessive fluid must never be forgotten.

This line of treatment I wish to emphasize particularly, because it is still far too common to meet with cases that have been treated by rest in bed for a month and the application of iodine. The former is unnecessary and the latter worse than useless, since the skin is rendered unfit for massage. After a month of this treatment the joint is often still distended with fluid, while the muscles are markedly wasted and will require prolonged treatment to restore them to their proper size and strength. As often as not the knee has been kept slightly flexed on a pillow, and full extension is impossible until the tissues at the back of the joint have been gradually stretched. Flexion due to this cause is distinguished from that due to mechanical obstruction by the fact that forcible passive extension causes pain at the back of the joint instead of the front. Rest is unnecessary in the milder cases, and even in the more severe walking can usually be indulged in after twenty-four to forty-eight hours. The amount of pain induced by walking should be our guide. We are not dealing now with gross rupture of ligaments. Active movements should be encouraged as soon as the patient can manage them. If walking be indulged in as early as possible, and electrical treatment carried out from the first, the muscles are never allowed to waste, and recovery is rapid. Golf and the more violent games which involve sudden twists and turns must not be allowed till the joint is free from fluid and the muscles are as large and as hard as those of the other leg. Rowing and cycling may be indulged in much earlier, and are useful and safe. Passive movements are hardly required if treatment is efficient from the first. In the nervous patient, and when active treatment has been delayed for any reason, they may be necessary. Gentle measures are usually better than violent.

The results of inefficient or injudicious treatment of a synovitis are chronic fluid, quadriceps insufficiency, adhesions, and occasional pain. The longer the knee remains distended with fluid the greater the laxity of the capsule and its supporting tendons, and the greater the difficulty in getting rid of this waterlogged condition of the joint. The fluid may have disappeared and yet the muscles be in poor condition. This wasting gives rise to a feeling of weakness, difficulty in negotiating stairs, especially descending, while there may be sufficient instability to give rise to symptoms which may easily be mistaken for cartilage trouble. Faradic treatment and exercises must be persevered with for weeks or even months before the muscles are completely restored to full vigour.

Adhesions should be averted by restoration of full movement as early as possible. If present, however, and the injury be fairly recent, perseverance with physiotherapeutic treatment will probably cause them to yield, but if some few weeks or months have elapsed a manipulation under an anaesthetic will be necessary. Gas is unsuitable, ether is preferable, since absolute relaxation is necessary. What are the indications? Limitation of movement (not forgetting rotation), local pain when approaching the limits of motion, or both of these, and sometimes recurrent fluid. The longer the history the more reason for manipulating, and, if this fails, for exploring the joint. It is well known that a common site for local minor adhesions is the region of the internal lateral ligament with limitation of flexion and local pain, and that manipulation in such cases is usually successful. In doubtful cases manipulation should be given a trial before resorting to operation. It is not very uncommon for a patient to complain of occasional pain on certain days or after exercise, for months after an injured knee appears to have been completely restored to normal. Bruising of the articular ends of the bones is the probable explanation of this, in older patients osteo-arthritis will develop in the course of time.

Now let us consider some of the injuries to special structures which may complicate the synovitis. A fairly common injury is *strain of one lateral ligament*, usually the inner. The upper end of this ligament is damaged sometimes as commonly as the lower. Local tenderness and pain on exerting a valgus strain on the knee, with or without some lateral instability, will be present. In the average case seen shortly after the accident, it is worth while applying an outside splint to prevent the slight

abduction of the leg, and a firm pad over the ligament, for a few days, when the patient may be allowed up, provided the inner margin of the heel of his shoe has been wedged. In addition, the usual treatment for the synovitis is carried out from the first. The vastus internus, sartorius, etc., on the inner side will require special attention. The possibility of adhesions must not be forgotten. Be sure that full rotation and flexion are restored. Complete rupture of the lateral ligament and capsule on one side, allowing the joint to be gaped, is best treated by operation and suture, as far as possible, of all the torn structures. Such a rupture can occur without serious damage to the crucials.

The anterior crucial—we need not worry about the posterior to-day—is tight in extension and in extreme internal rotation. It is damaged either by over-extension of the joint or by severe lateral bending, when it yields after one or other lateral ligament has given way and the bending strain continues to operate. In either case the ligaments generally have been badly damaged. If it is not deemed necessary or advisable to suture a lateral ligament, the knee should be put in plaster, in extension, for six weeks. The result of such treatment after a complete dislocation of the joint may be surprisingly good, provided the knee is immobilized early. There is general agreement that it is useless to try and suture a torn crucial. If this ligament is found damaged some weeks or months after injury, constructing a new ligament out of fascia lata (Hey Groves-Alwyn Smith operation[1]) must be considered. Anyway, the condition of the muscles will be a decisive factor in the final result. Sometimes the crucial ligament, instead of tearing, elevates a fragment of bone from the non-articular area in front of the tibial spine; this will be referred to again later. The treatment of this is by operation.

Semilunar Cartilage Lesions.

The internal is far more frequently damaged than the external, probably because a valgum strain is so common. A small amount of lateral mobility in a slightly flexed knee is normal; in many knees, even and perhaps especially so in those who excel in the more violent games, this mobility is more than slight. How does the damage to the semilunar cartilage occur? When the inner side of the knee is forcibly gaped the cartilage is sucked in towards the centre of the joint by atmospheric pressure, and is then more readily caught between the bones. The inner condyle, instead of gliding over it, tears and carries with it a portion, or even the whole, of the cartilage. Twists of the femur on the fixed tibia are blamed by many surgeons for the damage, and no doubt this is correct in most cases, but violent extension, with or without combined rotation, must also be a factor in some. Preliminary damage to the internal lateral ligament, and partial freeing of the cartilage, to which the former is attached, is improbable, in view of the fact that damage to this ligament is certainly not very common in cartilage lesions, and would not explain many of them. On this point I entirely agree with my friend Mr. Bristow.[2] The posterior end of either cartilage may be damaged by abrupt flexion of the joint as well as by a twist.

The actual lesions found at operation vary considerably, but the commonest are, first, the so-called "bucket-handle," where the cartilage, or a strip of it, is freed through the greater part or the whole of its length, but is left attached at its extremities; and, secondly, a freeing of a part or the whole of the anterior extremity. A bucket-handle lesion of the posterior part only is not infrequent, and must be remembered when at operation the visible anterior portion appears to be normal. A double bucket-handle of either cartilage—two free strips attached only at their extremities—may occur, while a lesion of both cartilages in the same knee is occasionally met with. In one patient I removed all four cartilages; in three of these, at any rate, a definite traumatic lesion was present. The history one likes to get is that of a definite trauma resulting in immediate locking of the knee in moderate flexion, unlocking of the joint abruptly—with or without the aid of an anaesthetic—the unlocking being accompanied by a snap or click, and recurrence of this sequence of events on at least one occasion. Unfortunately such a clear history is by no means always obtained. The more indefinite the history the greater the need for caution, it being remembered that in most cases the question of operation depends upon the history alone. The abrupt unlocking of the joint, particularly when accompanied by a snap, is often more convincing than the actual locking. In some the knee simply gives way with or without a click.

The history is apt to be less definite when the external cartilage is at fault. Tenderness may be present after a fairly recent injury, and is localized to the spot where the remaining attachment of the cartilage to the tibia and capsule has been strained. A common spot for this is the margin of the tibia a little to the inner side of the ligamentum patellae, as insisted on by Sir Robert Jones on many occasions. This corresponds to the anterior attachment of the internal semilunar cartilage, which must be strained when a bucket-handle type, for instance, gives rise to locking. If full extension is impossible this must be obtained by manipulation, with or without the aid of an anaesthetic, and then the synovitis should be treated in the routine way. The patient need not be kept in bed. I can confirm the experience of several of my friends that a knee that habitually snaps on flexion and extension is the seat of a lesion of the external cartilage. This is true of children as well as adults. Recurrence of locking due to a damaged cartilage, though the rule, is not inevitable. The cartilage may be nipped without being torn or grossly loosened, so operation should be delayed—provided the knee can be fully extended—till a second locking occurs. Always have radiograms taken to exclude injury of the bones. Nipping of a fat pad may give rise to similar symptoms. If the symptoms have been indefinite, but have recurred from time to time, or fluid has persisted or recurred over a period of a couple of years, the joint should be explored; in some cases operation is justifiable much sooner.

As to the operation, I now prefer the vertical incision for many reasons, one of which is the ease with which a wide exposure of the joint can be obtained, if desired—for example, when an unexpected articular cartilage lesion is discovered—by prolonging the incision upwards beside the patella and into the quadriceps tendon. This enables one to displace outwards the patella, as suggested by Fisher.[3] When it is desired to examine carefully the external cartilage in addition to the inner, it is better to make a second incision on the outer side. The split patella operation is better avoided.

The classical *loose body* is traumatic in origin, and consists of a fragment broken from the joint surface of a bone. The typical symptoms consist of a momentary locking, followed by a varying amount of effusion. The original trauma need not be severe. Such a body, even though not giving rise to much in the way of symptoms, should be removed, in order to avoid the inevitable osteo-arthritic changes; if the joint is already arthritic the changes will be aggravated by the loose body if left in the joint. The body usually consists of bone and articular cartilage, the former dead, the latter living and growing, nourished by the synovial fluid. Sometimes the body contains no bone and gives no shadow in a radiogram. It is often impossible, particularly in an old-standing case, to locate the site from which a loose body has been broken without making a wide exposure of the joint, and this is usually inadvisable and unnecessary.

Damage to the articular cartilage is far more common than is generally considered to be the case. As already stated, bruises of the articular surfaces account for some of the cases of persistent or intermittent pain occurring for long periods after injury. Portions of articular cartilage, with or without a flake of underlying bone, are often separated, completely or incompletely, by violence on the football field in adolescent and adult males. The loose piece may look as if it had been punched out by a cheese taster, the hole having abrupt and only slightly shelving edges. A slipping patella may result in damage to the outer condyle or the deep surface of the patella. The latter bone, if examined during the course of an operation, will not infrequently show a sodden fissured condition of its

artilage, more often on the inner half, with cracks reaching down to the bone.

A not uncommon site for damage is the outer part of the inner condyle, adjacent to the intercondylar notch. This results from external violence, which drives the tibia rearwards, the tibial spine impinging against the margin of the inner condyle, a portion of which is sheared off. Frequently the cartilage is left intact at one spot, so that the fragment remains more or less *in situ*. It is this condition which was described in 1888 by Koenig, who thought it resulted from an inflammatory process, a quiet necrosis, and called it osteo-chondritis dissecans. Most surgeons nowadays are convinced that these cases are purely traumatic. A subsequent trauma may complete the separation, setting the flake free as a loose body. If the flake remains *in situ*, persistent fluid is the chief feature, the true nature of the case being revealed by x rays. The partially detached fragment should be removed and the edges bevelled off. The prognosis is good—far better than might be expected. The exposed margins of the two condyles may be chipped off by a kick or blow. Twice I have seen the posterior end of one condyle flaked off, once by violence which seemed quite inadequate. Sometimes the *spine of the tibia* suffers rather than the femur from a shearing movement between the two bones, one or other tubercle of the spine being cracked off, without much displacement as a rule. The severity of the injury, rather than the small fracture itself, accounts for the somewhat slow recovery in these cases. Only if extension is blocked should the joint be opened.

Another type of injury, grouped as a rule, and quite correctly I think, with fractures of the tibial spine, consists in the elevation of a portion of the non-articular zone in front of the spine. In such cases forcible hyperextension of the joint has resulted in the avulsion of the zone to which the anterior crucial is attached, instead of a tear of the ligament itself. The fragment is elevated in front, hinging on its posterior end. Full extension is usually impossible, probably because the elevated bone fragment impinges on the fat pad. These cases should always be operated upon, the fragment being pegged or sutured down into place. As regards the patella, it is not very uncommon to find a crack or fissured fracture which has been overlooked. It is well to remember, however, that very occasionally the patella ossifies by two centres; this abnormality is bilateral.

Another common type of synovitis is due to a mild and unsuspected *osteo-arthritis* which has been *made to flare up* by a recent trauma. The diagnosis is usually easy, in view of the age of the patient, the absence of any special point in the history beyond the mild trauma, perhaps the presence of physical signs of osteo-arthritis, and, lastly, the changes, slight perhaps but definite, which are seen in the radiograms. It is this type which gains so much from *stable* treatment, for the tone of the muscles is of paramount importance, and yet cannot be regained by exercises without over-using the joint, the one thing which must be avoided at all costs, particularly in the early stages of recovery. Heat in one form or another is also an essential part of the *treatment*; it undoubtedly relieves the pain. Radiograms should always be taken, for loose bodies are, of course, not uncommon in osteo-arthritis, and their removal may be advisable. If giving rise to crises, however mild, they should be removed. If causing no obvious symptoms, it small, it situated at the back of the joint, if the general arthritis is gross, or the patient elderly, they can often be left alone. Each case must be considered on its merits, with the help of good radiograms.

The knee is subject to that curious condition called *chondromatosis*, the chief feature of which is the presence of a number, often a large number, of loose bodies in the joint. These bodies are formed in the synovial membrane, and later become extruded, more or less, into the joint cavity. They consist of nodular masses of cartilage with calcified or ossified centres, and vary greatly in size, many being minute. For the most part they lie in recesses, held together by colourless vascular adhesions, which are really outgrowths from the synovial membrane. In spite of their number and enclosed size, and the fact that they are often known to have been present in the joint for many years, the general osteo-arthritic changes may be surprisingly slight.

Cysts of a semilunar cartilage have been spoken of as a ganglion. Trauma probably plays a part in their production, and certainly aggravates them when present. With rest they may diminish in size, or even disappear, only to enlarge again on resumption of active exercise. The external cartilage is almost invariably the one affected, the cysts occupying its peripheral border and the adjacent tissues. In a typical case a characteristic tense fluctuating swelling is found on the margin of the tibia, overlapping the joint line, and just in front of the external lateral ligament. They may give rise to no symptoms, but many patients experience discomfort or actual pain during and after active use of the knee, sufficient in many to interfere with work or play. In the adolescent without symptoms they may be left alone to see if they will disappear. I have known typical swellings disappear entirely and permanently in two cases. In the young adult, in whom they are usually met with, they generally require removal, and this means the excision of a third or more of the cartilage.

Knee Cases in Childhood

Lastly I want to refer to some of the difficulties met with in the diagnosis of knee cases in childhood. In spite of their many tumbles, serious damage to the knee-joint is surprisingly uncommon in childhood, yet cartilage and other lesions do occur in the young, and perhaps more frequently than is generally believed. Symptoms seem to be less definite than in the adult—complete locking for instance, is excessively uncommon in children. My experience, admittedly small, seems to show that, in childhood, developmental abnormality of a cartilage favours the incidence of symptoms, with or without traumatic lesions; in addition, and that the external cartilage is far more commonly affected—the reverse of what is true in adult life.

Apart from a transient mild synovitis following a simple strain, in childhood there appear to be three main types characterized respectively by chronic or recurrent fluid, clicking in the joint, and recurrent symptoms more or less comparable to those familiar to us in the adult cartilage case. In the adolescent we also meet with "slipping patella" and with damage to the articular end of the femur—the so-called osteo-chondritis dissecans already referred to. I have not met with this latter condition under 14½ years. To take the clicking knee first, a typical example will suffice.

A child of 6 was seen on account of snapping in one knee-joint and slight wasting of the thigh. The snap occurred at about 70 degrees of flexion, and occurred on extension at about the same point. When it snapped something seemed to jump on the outer side of the joint. Trouble with the external cartilage was diagnosed, but in view of the age of the child, and the absence of any fluid, nothing was done. She improved, and for considerable periods the snapping apparently ceased, only to return. Two years after the first examination, in addition to the snapping, the knee was said to have given way on several occasions, and the joint became distended with fluid. Operation showed that the external cartilage only extended from its anterior attachment as far as the external lateral ligament, where it failed away to nothing; the posterior half was entirely absent so far as could be seen through an incision behind the lateral ligament. The anterior half was unusually thick, but not torn or displaced. Its removal was followed by a complete and lasting cure of all symptoms.

It is with the first type, that with chronic swelling and no special features, that difficulties arise in diagnosis. The two other conditions which have to be distinguished from the purely traumatic case are subacute or chronic infective arthritis and tubercle. In both of these a history of trauma at some time or other is common enough. It is when the trauma is remote that the difficulty arises. The appearance of the child and the family history may favour tubercle. Definite heat in the joint is against tubercle, while the presence of fluid is definitely against tubercle except in its later stages with abscess formation, when the correct diagnosis is obvious. The presence of septic foci in the tonsils, the commonest focus from which infection arises, may be an important factor. Briefly, the local conditions typical of each are in pure traumatic or mechanical defect, fluid, in infective arthritis, fluid, pus

some synovial thickening; in tubercle, definite synovial thickening and no fluid.

It is impossible to discuss the treatment of these cases fully, but, when difficulty arises, be on the safe side and rest the joint for a time. When it is impossible to exclude tubercle with certainty, though a diagnosis of another infection is favoured from the local signs and the presence of infective tonsils, arrangements should be made for enucleation of the tonsils without delay, and for removal at the same time of a fragment of synovial membrane through a small incision. Even when the tonsils have been removed this exploration of the joint may occasionally be advisable, but it is more often necessary in older patients when fluid is more likely to result from tuberculous infection, and the diagnosis is more difficult. Microscopic examination of the synovial membrane, and injection of a portion into a guinea-pig, appear to be more reliable tests than examination of fluid withdrawn from the joint, when this is possible.

CAESAREAN HYSTERECTOMY.

WITH THE REPORT OF A CASE OF PRE-LABOUR SEPTICAEMIA, AND OF CARCINOMA OF THE CERVIX IN LABOUR.*

BY

BETHEL SOLOMONS, M.D., F.R.C.P.I.,

MASTER, ROTUNDA HOSPITAL, DUBLIN.

ALTHOUGH the indications for this operation are extremely limited the time has come for a reminder of the occasional necessity for its performance. The operation, although not very recent in discovery, is not very ancient: several workers adopted various procedures before it was really brought to public notice by Porro in 1877. Of his 138 cases 77 were fatal—that is, a mortality of 55 per cent. To Sanger and Leopold credit must be given for drawing attention to the fact that hysterectomy is usually unnecessary, and for making the modern Caesarean operation the "comparatively safe" procedure that it is at present. One of the reasons for this communication is to deprecate a certain tendency to radical measures, when milder methods are safer both as immediate and as remote risks.

The following have been suggested by different obstetricians as possible reasons for performing Caesarean hysterectomy:

1. Fibroids, with or without degeneration.
2. Carcinoma.
3. Sterilization.
4. Accidental haemorrhage.
5. Placenta praevia.
6. Rupture of the uterus.
7. Contraction ring dystocia.
8. Bad contraction of uterus after Caesarean section.
9. Neglected shoulder presentation.
10. In the presence of a faulty Caesarean scar.
11. Osteomalacia.
12. Decompensated cardiac disease.
13. In association with section after a ventral fixation.
14. Sepsis.

Fibroids.

It is a golden rule, so far as fibroids are concerned, not to interfere with them if possible in pregnancy, labour, or the puerperium. Sometimes, however, because of acute and unbearable pain, it is necessary to remove uterus and foetus at any time, usually about the sixth month; this, of course, must only be done after very careful thought. If the pain is so severe that something must be done, the alternatives are an endeavour to remove the tumours in the hope that the patient will carry on to full term, and we have carried out this procedure with success on several occasions; if this is impossible, the uterus should be emptied of the foetus; two or three months later myomectomy is done, in the hope that a further and successful pregnancy will occur at some future time. The removal of the foetus, however, is seldom indicated.

When a patient comes under observation at full term, if vaginal delivery appears impossible because either of the possibility of tumours low down causing definite dystocia, or of the number of upper segment tumours which may cause inertia, it may be necessary to perform the Caesarean operation. The question "to leave or not to leave" the uterus is urgent. If we do not remove it another operation will be necessary later, or the tumours may degenerate in the puerperium; if we remove it we are adding to the danger of the operation. Caesarean hysterectomy for fibroids is an operation to be approached with extreme caution; many tumours are infected, and our experience in this class of case has not been pleasant. We prefer to adopt temporary measures, either allowing the woman to deliver herself, or performing a simple lower segment Caesarean operation with or without drainage, with the idea of removing the tumour or tumours at a later date.

Nyhoff[1] reports 19 hysterectomies in 250 Caesarean sections, and to our mind some of these hysterectomies are very deserving of criticism; three were for myoma uteri, but in his lengthy paper, which was very kindly translated from the Dutch for me by Mrs. Van Stockum, he does not give full data.

Anderodias and Loubat[2] reported an interesting case where pregnancy with fibroids was carried to term under great difficulty. At the Caesarean operation stinking liquor amnii was encountered, so hysterectomy was performed. It seems to me that the lower segment operation in this type of case should be perfectly safe without hysterectomy if the upper abdomen is not touched.

Carcinoma of the Uterus.

From a really practical point of view carcinoma of the body of the uterus need not be considered. To my mind the correct treatment of carcinoma of the cervix in the early months is hysterectomy without opening the uterus; if the condition is discovered near viability the cervix should be kept as clean as possible until the child is viable, when a true Caesarean hysterectomy should be done.

Recently at the Rotunda Hospital a woman, aged 28, a 5-para who had had four healthy children, was admitted complaining of a foul-smelling discharge. She appeared ill. The foetus was about 28 weeks, and the foetal heart was audible. On vaginal examination a freely bleeding cauliflower mass was discovered springing from the cervix. The os was about four fingers dilated and the membranes were ruptured. Believing that the haemorrhage which occurs in this type of case when delivered vaginally would kill the patient, Caesarean section was decided on. The uterus was opened, after which it was intended to remove the infant and then the uterus with the placenta *in situ*; but the latter presented; it was speedily removed, after which a live baby, weighing 2 lb. 13 oz., was delivered. The head showed a marked caput succedaneum, caused by the definite disproportion set up by the enormous growth. It was then found that the tumour was of a size larger than a clenched fist, and that it had retracted high over the head, and total hysterectomy was quickly done, for the patient was in a very low state, the pulse rate reaching 130 on occasions. Drainage was effected by gauze in the parametria and a cigarette drain in the cul-de-sac. She recovered from the immediate effects of the operation and has left the hospital. The infant has put on weight and appears likely to live. The pathological report was as follows.

Macroscopically.—The uterus is enlarged, and shows a recent operation wound on its anterior aspect; it corresponds to the post-partum uterus. There is a large cauliflower-like mass springing from the external os; on opening the cavity the uterus is filled of blood clot, but presents no other abnormality. The tumour at the cervix is white in colour; on section it is outlined from the cervical tissue; the proliferation appears to be entirely exophytic.

Microscopically.—Sections show solid columns of rather large cells closely packed together and infiltrating the surrounding tissues. There are no cell nests present, but from the appearance of the cells and their arrangement there can be no doubt that they originated from the squamous epithelium of the portio. A line of cleavage between the malignant process and the cervical tissue is well marked, and is surrounded by a zone of small round-celled infiltration. The cervical tissue towards the uterus shows scattered areas of round-celled infiltration.

When the patient is at or near full term before labour starts Caesarean hysterectomy should be performed. We believe this is the best treatment, although section followed at a later period by the application of radium may certainly be considered; but the application of radium to the cervix before the birth of the child must be approached with caution. Goldstein and Murphy,[3] in a recent com-

* A paper read before the Royal Academy of Medicine in Ireland.

unication, drag special attention to the possibility of great danger for the child after radiation. Among thirty-eight unhealthy or defective children born after post-conception irradiation therapy, sixteen microcephalic idiots were found. Only two of the mothers in these cases received radiation in late pregnancy. The mother in the special case reported was six months pregnant, and received 150 mg. of radium filtered with 1 mm. of brass and 5 mm. of aluminium for twenty-four hours. The history of the microcephalic idiot up to 12 years of age is given. Murphy[4] in another paper concludes, from the examination of 625 pregnancies in women subjected to irradiation, that because of defects in off-spring, the pregnant uterus should never be subjected to radio-therapeutic exposures. This excludes x-radiation for diagnosis.

Sterilization.

Caesarean hysterectomy has been suggested as a means of sterilizing a patient when this is indicated. In the masterly review of this subject given by Muret[5] it is not recommended. In our practice, when we decide that sterilization is necessary, we adopt much simpler means: after doubling the tube it is tied with a silk ligature. Audebert and Fournier[6] recommend hysterectomy, while Nyhoff reports a case of abdominal fistula and hernia from a previous Caesarean operation for which he performed hysterectomy. Many writers suggest sterilization by hysterectomy because of a weak scar. There should be no weak scar; if it is weak, it can be resected; hysterectomy should not be done.

Accidental Haemorrhage.

During the past decade, and even up to recent years, obstetricians still recommended Caesarean hysterectomy for this condition. We believe that such drastic treatment is utterly unnecessary. We have participated in the radical and palliative measures for this disease. We have gone through the mill, starting with Caesarean hysterectomy for concealed haemorrhage; we have assisted at the first Caesarean section without hysterectomy for concealed haemorrhage, and have seen success follow its performance; we have arrived at the far more successful results which follow the simple methods at present in use in the Rotunda, and we are of the absolute and dogmatic opinion that while there may be a minute place for Caesarean section there is no place for Caesarean hysterectomy in the treatment of accidental haemorrhage; the same remark applies with stronger force to placenta praevia.

Toxaemias of Pregnancy, including Eclampsia.

Caesarean section is practically never done at the Rotunda for this complication of pregnancy, and there is therefore no reason for doing Caesarean hysterectomy. Those who advise section suggest that the uterus should be removed in some instances because of its atonic condition; as we have stated, we do not concur in this opinion.

Rupture of the Uterus.

This is one of the true indications for the operation. As is well known, after removing baby and placenta, we practise "plugging the rent" when possible—that is, when the rent is consonant with the possibility of plugging and when the baby is not altogether or nearly entirely in the abdominal cavity. If the baby is completely or nearly completely out of the uterus, we advise its removal by the abdomen, followed by hysterectomy and drainage of the stumpetria by the vagina, in addition to abdominal drainage. This operation must be speedily done, and the subtotal operation is usually sufficient. Among our cases, all of which survived, may be mentioned the last, which occurred in a 10-para. The signs of threatened rupture had not been recognized, and rupture occurred by attrition through the lower portion of the posterior wall. The foetus failed to stop the haemorrhage, so laparotomy was performed, and a quick hysterectomy with drainage was followed by recovery after a somewhat stormy convalescence. The total operation is rarely ever necessary.

Contracted Pelvis Dystocia.

One of Clifford White's cases was selected by this method, but opinion on this subject has been revised in a recent one.[7] If Caesarean section is necessary at all, we cannot see the need for removing the uterus by subsequent hysterectomy in addition. A hysterectomy does relieve the "uterine cramps" and even if infection has occurred, drainage will prevent the occurrence of any serious complication.

Unsatisfactory Contraction of the Uterus after Caesarean Section.

This is mentioned by Nyhoff as an indication, but here again we cannot agree to place this on our list. Hot towels, haemostatic drugs, and pituitrin, in addition to plugging of the uterus, will obviate the necessity for such a radical procedure.

Neglected Shoulder Presentation.

It has been our custom to teach students that if the baby is alive, version can be done, if dead, decapitation; but it must be remembered that in the latter operation great caution must be exercised. Manipulations of too violent a nature will rupture the uterus when the lower segment is very thinned.

What is the procedure when the baby is alive in neglected shoulder presentation? The answer is: If such a state of affairs should arise (and we have never seen it) the lower segment Caesarean operation would be our choice. Is hysterectomy ever indicated in addition? Our answer is to the negative. A neglected shoulder presentation occurred in our practice[8] in which hysterectomy was necessary later because of puerperal sepsis. This might be taken as showing a definite place for Caesarean hysterectomy in the treatment of this condition, but we do not agree. Most cases of neglected shoulder will not require hysterectomy afterwards; therefore, why *do* it at all?

Other indications may be mentioned. Nyhoff, already referred to, had a case of a woman of 42 who had had sixteen confinements. He did Caesarean hysterectomy to avoid recurrence of rupture which had occurred in a previous labour. Surely, if section were indicated, sterilization would have been more simply accomplished by tying the tubes.

Osteomalacia.

For osteomalacia Caesarean hysterectomy has often been done, but several patients who seemed to require hysterectomy were treated simply by removal of the ovaries. Van Velitz had a case where the haemorrhage was severe from the uterus at the time of section that he removed the organ. We do not meet with osteomalacia in Ireland.

Decompensated Cardiac Disease.

If section is indicated for this disease, hysterectomy in addition will lessen the chance of uterine sepsis, and will remove any discomfort or stress associated with the puerperium. Falkner[9] has recently mentioned a very successful case of this kind, and it is certainly most practical.

Occasionally after a badly performed suspension (not one with *posterior angulation* of the uterus) even Watts Morris[10] has reported to the Academy a fatal case in which we believe the patient might have been saved if hysterectomy had been performed in addition to section.

Sepsis.

Sepsis in the uterus before labour may be regarded as a definite indication for Caesarean hysterectomy. It is extremely rare, and a case which recently came under our notice is of such great interest that it is reported in full here. Septic organisms may invade the uterus before the end of labour as I after the rent has been ruptured, or infection already in the vagina may spread to the uterus from a septic cervix, especially with gonococcus as the cause. The uterus may also get infected from vaginal manipulation of any sort, as I have had occasion to point out in the past as the chief offender. Instrumentation of any kind must be viewed with suspicion, and it is a wise rule to be repeated the question was [illegible] examination was [illegible] be discussed.

[illegible] The patient was a woman aged [illegible] Caesarean section [illegible] the infant died [illegible] [illegible] [illegible]

ether, the following data were elicited: promontory not reached, the head pushed to the level of the ischiatic spines. Three bougies were inserted. On June 7th, as labour had not started, the bougies were removed and four fresh ones inserted, but in spite of this, as well as oil and quinine, there was no labour. On June 10th she left the hospital against our wishes. She was normal in every way.

On June 21st she was readmitted, and said she had felt quite well until 9 p.m. on June 20th, when she had a rigor. She had another at 9 a.m. on June 21st, when the temperature was 102° F. On her readmission she appeared ill, and as it was thought possible she had influenza, aspirin was administered every four hours.

On June 22nd, soon after midnight, she had a very severe rigor, which lasted five minutes. Temperature 101.2°, pulse 110, respiration 24; profuse sweating, no oedema. The tongue was clean and there were no chest or abdominal symptoms. Blood was taken for culture, and 20 c.cm. of antistreptococcus serum and 7.5 grains of quinine were administered intramuscularly. No history of vaginal discharge could be elicited. The foetal heart was 165 to 170, but there were no pains or history of labour. About an hour later the membranes ruptured, solid meconium came away, and she complained of sudden abdominal pain. On examination the uterus was tender. Careful interrogation elicited the fact that coitus had taken place on June 12th—that is, five days after the second insertion of bougies. A diagnosis of coitional sepsis along the track of the bougies was made, and in order to save her life and that of the child, who showed danger signs (meconium, quick foetal heart), Caesarean hysterectomy was decided on. At 2.35 a.m. on June 22nd an abdominal incision long enough to allow exteriorization of the uterus from the symphysis upwards was made. The abdominal wall was protected by coverings, and the intestines by large wipes. After the uterus had been delivered outside the abdomen, the infant was delivered alive; the placenta was left *in situ*, the uterus stitched, and a speedy total hysterectomy done. The parametria were drained by the vagina, and a tube was placed in the cul-de-sac and brought out through the lower abdominal incision.

The temperature and pulse were normal from the time of the operation, but the baby developed a streptococcal rash and died on the twenty-fourth day.

Sections from the placental site, which was rather low, showed dense infiltration with inflammatory cells. Here and there oedematous areas and old interstitial haemorrhages were found, especially near the cervix. There were enormous numbers of plasma cells in all the sections. No organisms were found, but there was marked inflammatory reaction. There were no spirochaetes in the placenta. The blood and uterine cultures were negative.

An examination of the husband revealed pus cells in prostatic smears.

This was evidently a case of true infection from coitus along the track of the bougies. It must not be regarded as necessitating the abolition of the bougie method of inducing labour; it should be regarded as a warning not to allow hospital patients to be discharged after bougie failure; if the patient persists in leaving, she should be warned that she will not be readmitted.

The treatment carried out was drastic, but it was life-saving; there was no doubt about the diagnosis, and if heroic measures had not been taken death of both mother and child seemed to be a certain outcome; in fact, in true pre-labour sepsis, where the upper segment becomes involved, the only treatment is Caesarean hysterectomy with thorough drainage.

A curious coincidence was elicited in this case. The husband of the patient had been married before; his wife had died after Caesarean hysterectomy for accidental haemorrhage at the time when this treatment was the most customary.

The notes of the cases reported were taken by my assistants Drs. Taylor and O'Donel Browne; the pathological data were recorded by the pathologist to the hospital, Dr. F. S. Bourke.

It is sometimes customary to give statistics at the conclusion of a paper such as this. As the number in the Rotunda reports is so small we do not propose to enter into this phase of the subject.

Summary and Conclusions.

1. The indications for the performance of Caesarean hysterectomy are given.

2. The place of the operation for fibroids is small, but for carcinoma is very definite. A case of the latter is reported.

3. Sterilization by hysterectomy is seldom indicated, for other simpler methods are preferable.

4. Ante-partum haemorrhage and the toxaemias do not rank as indications at the Rotunda.

5. Rupture of the uterus sometimes demands its performance, but contraction ring dystocia and neglected shoulder presentation are not indications.

6. Sepsis pre-partum sometimes demands this radical procedure. An interesting case of coitional sepsis is described in detail.

MEASLES IN A MAN OF FIFTY-SEVEN.

BY

ARTHUR J. HALL, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE, SHEFFIELD UNIVERSITY.

In any country in which measles is more or less constantly prevalent its occurrence in an adult is as rare as its occurrence in childhood is common. The outbreak of measles in the Faroe Islands, recorded by Panum of Copenhagen, showed that adults are as susceptible as children. It was conveyed there in 1846, after an interval of sixty-five years, and 6,000 out of the 7,782 inhabitants were infected. Age was no bar; practically no one escaped who was exposed to it. In this country it occasionally affects young adults, but such cases are not common. The case here briefly narrated of a first attack of measles in a man in his sixth decade is so unusual that it seems worth recording.

On December 24th Mr. X, a married man aged 57, began to be feverish and out of sorts. Catarrhal symptoms, though not particularly noticeable at first, were present. The case was thought to be one of influenzal type. The temperature was slightly raised. On December 27th it fell somewhat, and he seemed rather better; also on the morning of the following day. The attack was thought to be passing off. In the evening of the 28th, however, the temperature rose to 103°, and a rash was noticed. On December 29th the rash was much more extensive, and the temperature 104°. There was also considerable bronchial catarrh. His medical attendant, Dr. Parrett of Thorne, recognized the nature of the disease as soon as he saw the rash. He was naturally surprised and a little anxious, because the patient had for some years been subject to bronchitis in the winter months.

On December 31st, as the temperature was still high, the pulmonary symptoms increasing, the pulse rate going up a little, and as there was also some cyanosis, Dr. Parrett asked me to meet him in consultation. The patient was mentally quite clear and alert. There had been no delirium at any time. The cough was very troublesome, and rhonchi were audible over the lungs, but there was no real dyspnoea. The pulse was 88 and regular. The face was dusky red, slightly cyanosed. The conjunctivae were injected, the tongue was an intense fiery red with white patches here and there. The rash was more marked on the face

neck, and trunk than on the limbs, and consisted of closely packed but discrete crescentic and irregular macules, showing innumerable typical bright red papules, many of which were distinctly petechial. This necessarily produced a considerable variety of colours, and as he was a big man, with a very long and broad back, the total effect of this large mass of brilliant colouring was unusually striking.

Prognosis was difficult. Measles at 57 years of age is quite outside one's experience. It seemed just possible that as this disease gives rise to the more severe bronchial complications in infancy it might also be more severe in this respect in the later years of life, especially in a person already subject to bronchitis. As, however, the pulse was only 82, and there were no signs of serious toxæmia, and as by the eighth day, the fever had probably reached its height, it seemed likely that the next few days would bring a general improvement. The only point of doubt was as to the possible extension of bronchial trouble. Our anxiety about this, however, was unnecessary, for in a few hours he began to improve, and after that continued to make an uninterrupted recovery.

It is interesting to surmise how and where he became infected, and still more how it was he had escaped infection earlier in life. As regards the former point, there was an outbreak of measles in the neighbourhood at the time, and an opportunity of infection seems to have been a journey in a public motor bus, just a fortnight before, to and from a neighbouring town some miles away. There were some children in the bus, but nothing is known as to who they were, or if any of them had the disease. Otherwise he led an unusually secluded life. Although married he had had no children. He lived in a large, rather isolated house, and had very few visitors. Curiously enough, his wife is said to have had measles twice, though whether either of the attacks occurred since marriage was not stated.

Students in taking clinical histories often forget to put down the patient's age, and when told to do so are apt to look upon their teachers as rather unnecessarily meticulous. As a matter of fact, in hearing the history of a case the experienced clinician unconsciously adjusts his thoughts to a certain group of cases directly he hears the patient's age; at any rate, he unconsciously eliminates a considerable number of conditions which he knows are not likely to occur at that particular period of life. Now and again, as in this case, it is the unexpected that happens. When it does, the ordinary clinical values become changed and require rather careful adjustment.

HIGH BLOOD PRESSURE AND CHOLESTERIN.

BY

T. HARRIS, M.D.KONIGSBERG., L.R.C.P.ED.,
PHYSICIAN TO THE LIVERPOOL HEART HOSPITAL,
AND

T. J. LIPKIN, M.D., CH.B.LIVERP., D.P.H., D.T.M.,
BIOCHEMIST TO THE LIVERPOOL HEART HOSPITAL.

Within recent years various attempts have been made to seek in blood chemistry the causal factor for hypertension. Adrenaline and its derivatives, sugar, uric acid, potassium and calcium salts, in abnormal quantities in the blood, each of these substances in turn has been held responsible for the hypertonic contractions of the vessels in cases of high blood pressure. The latest suggestion is that hypercholesterinæmia is responsible for the production of high blood pressure. According to Westphal[1] cholesterin in the blood circulation affects the vessels in such a way as to increase their susceptibility to adrenaline. The latter, of course, gives rise to hypertension. This author found in 4 per cent. of his high blood pressure cases an increase in the cholesterin content of the whole blood.

Thomas[2] injected rabbits with cholesterin and observed an increase in blood pressure. Thilditte,[3] who repeated the experiment, was not able to confirm the findings. While the authorities thus differ as to whether cholesterin actually raises the pressure, greater unanimity exists in regard to cholesterin as a factor in the production of arterial sclerosis. Tregubov[4] fed rabbits with cholesterin, and found, as many others have discovered before him, that arterial lesions did appear as a result of this feeding. Arterial pressure, however, did not rise in these cases. Shapiro[5] also looks upon cholesterin as the chief factor in the production of arteriosclerosis. He believes the increase of cholesterin in the blood is due to the activity of certain glands of internal secretion. Zacharias[6] prepared a kind of vaccine, the purpose of which is to dissolve cholesterin in the blood, and he claims a marked improvement in the condition of his patients as a result of this treatment, the blood pressure becoming low. Ashcroft[7] found an increased cholesterin content in the blood in the great majority of his high blood pressure cases, and he highly recommended rhodan as a solvent of cholesterin in the circulation.

Amidst all the turmoil of conflicting opinion one thing in fact stands out: arteriosclerotic vessels invariably contain deposits of cholesterin and calcium. Our observation is based on actual blood cholesterin content found in hypertonic cases. In our investigation we administered cholesterin to patients, first in the form of food rich in cholesterin content, and subsequently by intramuscular injections, taking the blood pressure reading and determining the cholesterin content of the blood both before and after administration of the substance.

Method of Cholesterin Determination.

On to a fat-free filter-paper disc, pierced in the centre and made to fit a specially constricted test tube containing 5 c.cm. of chloroform, is pipetted 0.25 c.cm. of oxalated blood. The tube is attached to a reflux condenser, and is immersed in a boiling-water bath. After thirty minutes the tube is detached from the condenser and cooled by putting under cold water, chloroform is added to the 5 c.cm. mark. To a similar tube 5 c.cm. of a standard cholesterin solution (8 mg. per 100 c.cm.) is added. To each tube is added 2 c.cm. of acetic anhydride and 1 c.cm. of strong sulphuric acid. The tubes are inverted twice to mix well and allowed to stand in cold water for ten minutes and compared in a Klett colorimeter.

The list of cases printed below gives the blood cholesterin of 11 hypertonic patients under observation at the Liverpool Heart Hospital. Cases with pronounced lesion of the kidneys were excluded, as it is known that these give a hypercholesterinæmia. We do not, however, for a moment suggest that all our cases are of the type of "essential" hypertony. We are definitely of opinion that it is quite impossible to differentiate clinically between "essential" hypertony and hypertony due secondarily to kidney disease for the kidney efficiency tests give only information in regard to failure of the kidney function, and not in regard to the existence or otherwise of disease of the kidney, and the presence or absence of a trace of albumin and occasional casts does not mean much either way. The normal variation of blood cholesterin within normal limits is between 160 and 200. It will be seen that only in one case did the cholesterin blood content exceed 200. At any rate, in all cases the blood cholesterin were found to be increased. It by no means follows that it is the cause of high blood pressure. It is quite possible that a high blood pressure in the liver might produce hypercholesterinæmia.

Blood Cholesterin of 11 Hypertonic Cases under Observation at the Liverpool Heart Hospital.

CASE 1.—C. M., aged 53. Blood pressure 225. Blood cholesterin content 172 mg. per 100 c.cm. of blood.

Clinical Notes.—Evidence of gross cardiac hypertrophy. The QRS complex prolonged. Left ventricular preponderance. Relative aortic and mitral regurgitation. Aortic second sound a very obvious feature of left basal systole.

CASE 2.—A. B., aged 58. Blood pressure 200. Blood cholesterin content 182 mg. per 100 c.cm. of blood.

Clinical Notes.—Typical case of high blood pressure. No evidence of left ventricular enlargement. Electrocardiogram normal.

CASE 3.—F. P., aged 49. Blood pressure [illegible]. Blood cholesterin content 234 mg. per 100 c.cm. of blood.

Clinical Notes.—Wassermann positive. Patient [illegible] of left ventricular preponderance. Electrocardiogram normal.

CASE 4.—R. B., aged 45. Blood pressure 220. Blood cholesterin content 196 mg. per 100 c.cm. of blood.

Clinical Notes.—[illegible] Aortic second sound is gross.

CASE 5.—C. M., aged 61. Blood pressure 225. Blood cholesterin content 250 mg. per 100 c.cm. of blood.

Clinical Notes.—Typical case of [illegible]. Electrocardiogram normal.

CASE 6.—E. A., aged 52. Blood pressure, 165/90; cholesterin blood content, 182 mg. per 100 c.cm. of blood.
Clinical Signs.—Trace of albumin. Left ventricle enlarged; aortic systolic murmur. Electro-cardiogram, apart from left ventricular preponderance, normal.

CASE 7.—R. C., aged 53. Blood pressure, 180/100; cholesterin blood content, 126 mg. per 100 c.cm. of blood.
Clinical Signs.—Accentuation of second aortic sound; left ventricle enlarged. Wassermann reaction strongly positive. Electro-cardiogram showed left ventricular preponderance.

CASE 8.—C. M., aged 59. Blood pressure, 200/60; cholesterin blood content, 164 mg. per 100 c.cm. of blood.
Clinical Signs.—Relative aortic regurgitation; abnormal QRS complex.

CASE 9.—M. S., aged 53. Blood pressure, 170/95; cholesterin blood content, 164 mg. per 100 c.cm. of blood.
Clinical Signs.—Trace of albumin; heart not appreciably enlarged; accentuation of second aortic sound and the mitral second. Electro-cardiogram normal.

CASE 10.—A. C., aged 50. Blood pressure, 200/110; cholesterin blood content, 164 mg. per 100 c.cm. of blood.
Clinical Signs.—Wassermann reaction positive. Second aortic sound accentuated; systolic aortic murmur. QRS complex abnormal.

CASE 11.—B. M. Blood pressure, 240/75; cholesterin blood content, 162 mg. per 100 c.cm. of blood.
Clinical Signs.—Double aortic murmurs. QRS complex abnormal. Wassermann reaction strongly positive. Trace of albumin.

At first we attempted to increase the blood cholesterin by giving the patients about a pound and a half of brain daily. As, however, the brain has many other constituents as well as cholesterin, it was decided to administer actual cholesterin to the patient intramuscularly; 1½ grams of cholesterin was administered in olive oil.

It is clear that cholesterin did not increase the blood pressure, although the blood cholesterin was enormously increased as a result of the injection.

Discussion.

The assertion that cholesterin causes a direct rise of pressure becomes untenable in the light of our observation. An enormous increase in blood cholesterin does not raise the pressure. Cholesterin is supposed to act on the adrenals. In this respect the following experiment in which one of us (I. H.) has taken part is interesting. As is well known, the effect of an intravenous injection of adrenaline in raising the arterial pressure is only a momentary one. A cat was given an injection of adrenaline and the pressure registered. After the systolic pressure had returned to normal, blood was taken from this cat and injected into another. The adrenaline effect was demonstrable again in the second cat, although when the blood was taken from the first animal this effect had already disappeared. This experiment demonstrates conclusively that although a large amount of adrenaline is present in circulation for some time, it is unable to raise the pressure for any length of time, for the simple reason that the organism counteracts any disturbance of the equilibrium in the level of blood pressure. The same thing happens if we attempt to reduce arterial pressure artificially. After venesection, for instance, within a few hours the blood pressure in most cases reaches the same level as before venesection, and we all know how difficult it is to raise the pressure in cases of hypotension.

All these facts go to show that the presence in itself of pressure-raising substances in the blood would never produce chronic hypertonia. High blood pressure is a condition in which, for some unknown reason, it is necessary for the tension to find an equilibrium at an abnormally high level. Luckily for the patients, all attempts on the part of the physician to disturb the new equilibrium usually end in failure.

As long as the real factors which produce high blood pressure are unknown the therapy of this condition will remain the miserable quackery it is to-day. At any rate, cholesterin is unable to solve the mystery of high blood pressure.

The other problem, as to whether cholesterin is the cause of arterio-sclerosis, has not been touched by our observation. There is little doubt that cholesterin is capable in rabbits of producing arterio-sclerosis, but whether this is applicable to man is another question. It is possible that the deposits of cholesterin found in arterio-sclerotic vessels are not the end-results of degeneration but have been caused by hypercholesterinaemia. It has been generally assumed that arterio-sclerosis of the larger vessels does not raise the pressure, but arterio-sclerosis of the small vessels effects an increase in pressure. Cholesterin when affecting the smaller vessels may indirectly raise the pressure. This would mean, of course, that arterio-sclerosis is the primary condition and the rise in pressure the secondary. There is, however, insufficient evidence to support such a hypothesis.

PASSIVE IMMUNIZATION BY MEANS OF SCARLET FEVER ANTITOXIN.

BY

JAMES M. COWIE, M.D., D.P.H.,
MEDICAL OFFICER OF HEALTH, BURTON-ON-TRENT.

AMONG the many difficult problems of fever hospital administration is that of safeguarding the patient admitted with indefinite symptoms against the risk of acquiring infection in hospital.

Three years ago the type of scarlet fever prevalent in this district was of so mild a character that many patients, on admission to hospital, showed only a very slight rash on the body; the temperature was normal; they presented no throat, tongue, or other signs; sometimes there were even traces of a rash. It seemed impossible at first to decide whether these patients were suffering from scarlet fever or not; but from the fact that a few developed the attack in hospital it became evident that at the time of admission the latter were not suffering from the disease.

Experiments were made with many methods of prevention. The Schultz-Charlton test merely corroborated what was usually known—namely, that a bright rash indicated scarlet fever; the Dick test was found to be of little value in the positive cases where the immunity had not had time to develop or where there was susceptibility to the disease. If the Dick test is repeated at the end of a week useful information is obtained, but susceptible patients are meanwhile exposed to infection. Active immunization by means of scarlet fever prophylactic develops too slowly to be of any real value; and barrier isolation, though employed to some purpose, was ineffective in wards where all the patients were not confined to bed.

The production of passive immunity by means of scarlet fever antitoxin was then considered. A small dose was said to give a passive immunity for ten to fourteen days. This period was not considered to be long enough, as "peeling" in many mild cases often does not occur until about the fourth week. If a dose is repeated within ten days there appears to be no danger of anaphylaxis, as sensitization to a foreign protein does not begin until after that period. The risk was lessened by administering only 2½ c.cm. at first.

The following routine method was therefore gradually adopted. All patients with indefinite symptoms received 2½ c.cm. of scarlet fever antitoxin on admission, a second dose of the same amount on the tenth day, and a third dose on the twentieth day. This was all that was necessary as a rule, but some received a fourth dose, and a few a fifth dose at the same intervals.

The doses have recently been increased to 5 c.cm., on the advice of the makers, though the smaller doses appeared to give good results. The number of patients that received treatment was 108; of these, 30 patients received two doses; 56 received three doses; 20 received four doses; and 2 received five doses. When typical desquamation occurred no further injections were given, and patients who showed no sign of desquamation by the fourth week were discharged. For various reasons some were detained for longer periods.

Classification of these 108 cases showed that 34 of them were probably not scarlet fever; of these 34 patients only one developed the disease, though all of them were exposed in the wards during the whole time. This patient was detained in hospital for a certain reason for forty days, but received only three doses of the serum, the last dose being on the twentieth day. Two days after discharge, on the twenty-second day after the last prophylactic dose, there developed a typical attack of scarlet fever. Henceforth all patients without definite signs received a prophylactic dose every tenth day until discharge.

Signs of Serum Reaction.—Signs of serum sickness have been almost entirely absent. Two patients developed a very mild urticarial rash on the thirteenth day after the first dose or the third day after the second dose; one developed a similar rash on the sixth day after the third dose; one had a rise of temperature of two degrees the morning after the third dose, and one had a rise of one degree on the day of injection of the third dose. None of the other cases showed adverse signs of any kind.

The method no doubt requires further testing, but in my application of it during the past three years it appeared to have been very successful, as ward infections have almost disappeared.

THALLIUM ACETATE AS A DEPILATORY IN RINGWORM OF THE SCALP.

BY

H. McCORMICK MITCHELL, M.B., C.M.ABERD.,

CONSULTING DERMATOLOGIST, CANCER AND SKIN HOSPITAL, LIVERPOOL; DERMATOLOGIST, WEST DERBY UNION HOSPITALS.

COMPLETE epilation of the scalp is generally considered to be the best and most expeditious form of treatment for ringworm of the scalp. Epilation by *x* rays has for many years been the method employed, and has given very satisfactory results, but it has some drawbacks which cannot be overlooked.

1. If there is any inflammation or pustular condition of the scalp *x* rays are, in my opinion, contraindicated as a depilatory agent. Moreover, in a small number of cases troublesome dermatitis follows their use, although the scalp may appear quite healthy, apart from the tinea, before radiation.

2. X-ray epilation is unsuitable for children under the age of 3, *since they cannot be kept still during the application.*

3. The most serious drawback is the permanent baldness which follows in some cases unless the treatment is given by someone highly skilled at the work.

I have been particularly struck with the variation in the output of *x*-ray tubes from day to day, and since the margin of error is small on either side the exact output of the tube should be carefully checked each day before work is commenced. The use, therefore, of any other method of producing depilation is worth careful consideration.

The depilatory action of thallium acetate has been known for many years. More than a quarter of a century ago Bourand used this drug in his clinic for the treatment of tinea capitis, but he seems to have abandoned it on account of its toxic effects on the patients. Recently its employment for the treatment of ringworm of the head has brought into prominence by A. Buschke, and it is most entirely due to his experiments on animals that the method has been made practical and safe.

The success and advantages of thallium acetate depend entirely on correct dosage. Buschke, after much research and in collaboration with L. Peiser, established the minimal dose for complete epilation of the scalp to be 8 to 9 mg. per kilo of the body weight. One dose is, in the majority of cases, quite effective in producing complete depilation, and can be administered either in sweetened water or mixed with food.

The number of patients treated by me has been 74: of these, 51 were under the age of 4; 9 were aged 4; 3 were aged 5; 7 were aged 6; 3 were aged 7; and 1 was 8 years old.

I have used throughout the preparation made by Kahlbaum of Berlin, who supplies the drug in tablet form containing 1 decigram, 1 centigram, and 1 milligram. I have varied the dose from 8 to 9 mg. per kilo of the body weight, and have found that the cases of failure, to which I shall allude later, were among those to whom I gave 8 mg. All that is required is to convert the weight of the child into kilograms and then multiply by 8, 8.5, or 9 milligrams, according to the dose intended, administering the required number of tablets dissolved in sweetened water or mixed with food.

The result of a single dose of thallium acetate is very striking. On the sixth or seventh day the hairs begin to loosen; by the fifteenth day they are coming out freely; and by the twentieth day depilation is almost complete, except for those fine hairs at the margin of the scalp which, in my experience, never fall out, and the same applies to the eyebrows and eyelashes. I have never administered the drug to an adult, so cannot say what the effect is on the hairs of the face, the pubes, and the axillae, but the experience of other workers seems to be that a dose sufficient to cause depilation of the scalp does not cause the hairs on the above parts to fall out. The infected stumps, as is the case after *x*-ray depilation, do not fall out so readily as the non-infected hairs, and this fact should be carefully borne in mind in the after-treatment. Removal of the affected hairs and stumps is most important in guarding against the reinfection of the new hairs, which appear much earlier than after *x*-ray epilation.

The routine treatment is as follows.

The urine in all cases is examined for albumin and casts; the weight of the child is converted into kilograms, and 8.5 or 9 mg. of thallium acetate per kilo of body weight is given in a little sweetened water or mixed with food. From the first day after the thallium is given the scalp should be washed daily with sp. saponis kalinus, or a 10 per cent. sulphur soap, and a fungicide ointment well

rubbed in. When the hair begins to fall freely Buschke recommends the use of tincture of iodine and a fungicide ointment on alternate days. I have followed this practice carefully in all my cases with great success.

After the eighteenth or twentieth day, when epilation is almost complete, a careful examination of the scalp is made with the ringworm lamp for the detection of infected stumps; these are removed as far as possible with the epilation forceps, and by adhesive strapping. It is advisable to use local treatment for ten or fourteen days after a careful examination with the ultra-violet beam has failed to detect the presence of infected hairs or stumps. If care is not taken to remove the infected hairs as quickly as possible the new hairs are liable to become reinfected, owing to the rapidity with which they appear after depilation.

Of the cases treated, 65 were cured after one dose of thallium acetate. In 10 cases the hairs were infected after the regrowth, and a second dose was necessary; in only one case had a third dose to be given.

Most of my failures occurred among my early cases, and I attribute my non-success to two causes: (1) At first I gave 8 mg. per kilo of body weight; this dose, in the light of my experience, is not sufficient to produce complete depilation, and I now invariably give 8.5 or 9 mg. (2) As the ringworm lamp was not available during the first few months for examination purposes, a number of infected stumps were not detected and removed, with the result that reinfection of the new hairs occurred. Since giving 8.5 or 9 mg. per kilo of body weight and conducting a daily examination for infected stumps with the ultra-violet beam after epilation is apparently complete, my results have been much more satisfactory.

One or two further points in connexion with this treatment are, I think, worth recording. (1) Children with dark hair are more difficult to depilate than those with fair hair; it is therefore advisable to give 9 mg. per kilo to the former class of case. (2) The hairs on the crown fall out less readily than those on the other part of the scalp, so that for ringworm in this situation it is also better to give the full 9 mg. dose.

Toxic Effects.

I have not seen any alarming toxic symptoms in any one of the cases I have treated; this was due partly to the fact that I insist on all patients remaining in bed for forty-eight hours after the thallium acetate has been administered, and partly to the fact that most of my patients were under the age of 4 years, as it is well known that young children are less susceptible to the toxic effects of this drug than older children.

The toxic effects most noticeable were apathy, loss of appetite, and drowsiness during the first two or three days, and pain in the joints, particularly in the lower limbs, appearing from the sixth to the tenth day. All these symptoms gradually disappeared without leaving any ill effects in any of the patients treated. All the children who showed toxic symptoms in any marked degree were more than 4 years old.

Summary.

As the outcome of my clinical investigation the following points might be emphasized:

1. Thallium acetate can be safely used as a depilatory agent where, on account of the age of the patients, æ-ray treatment is contraindicated.

2. Accurate weighing of the patient and correct dosage are most important.

3. The after-treatment is all-important in obtaining satisfactory results; the patients should be kept in bed for forty-eight hours after the initial dose of the drug, and from the first day of treatment the scalp should be washed daily with sp. saponis kalinus, or with 10 per cent. sulphur soap, and a fungicide application be well rubbed in.

4. Careful examination with the ultra-violet beam should be made after depilation is apparently complete, so as to detect any infected stumps which have failed to come out and which would reinfect the new growth of hair.

5. The use of thallium acetate should, as far as possible, be limited to children under the age of 5, owing to its toxic effects on those above that age.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HAEMATOMETRA WITH HAEMATOSALPINX IN ONE HORN OF A UTERUS BICORNIS UNICOLLIS.

THE rarity of this condition prompts us to record the following case.

The patient, aged 16, was sent to hospital on October 9th, 1929, by Dr. Crawford, for pain and swelling in the perineum.

History.—Menstruation began at 14 years of age; regular cycle of twenty-eight days, lasting five days, loss scanty. Last menstrual period September 10th, 1929. At the onset of menstruation the periods were free from pain, but during the last year there had been dysmenorrhœa of progressive severity. This pain, which started two days before the period, and continued throughout, was referred to the lower abdomen and perineum. On the second day of her last period the patient suddenly fell in a sitting posture, and a few hours later complained of severe pain in the right lower abdomen and perineum, which was worse than before. This pain persisted throughout the following month, making walking painful and sitting difficult; she also suffered from dysuria. At the onset of her next period the pain became so severe that she was sent to hospital.

Examination.—The patient was well developed but anæmic. In the *right iliac region* there was felt a *sausage-shaped swelling*, soft in consistency, irregular in outline, and tender to pressure, but with no rigidity of abdominal parietes. The right vaginal wall was bulged inwards by a globular swelling, which extended from the vaginal orifice upwards into the pelvis, and was definitely cystic. At the vault of the vagina the os externum could be detected, but no true cervix could be felt.

Bimanual Examination.—It was difficult to arrive at any conclusion, owing to the cystic swelling, the size of a large orange, occluding the vagina. As far as could be ascertained, there was a mass in the position of the uterus, continuous above with sausage-shaped mass below with the cystic swelling.

While awaiting operation, the patient suddenly developed acute abdominal pains with vomiting, the lower abdomen became rigid, and the patient took on the aspect of an abdominal crisis.

Operation.—Under general anæsthesia the peritoneal cavity was opened, when there was an escape of a large amount of altered blood. The uterus was enlarged to the size of a three months' pregnancy, and on further examination was found to be bicornuate; the left horn was the size of a normal virgin uterus, with a healthy tube and ovary. The right horn was slightly larger, and merged into a large globular swelling, which had burrowed down, lateral to the right wall of the vagina. The tube on this side was greatly dilated, and altered blood was seen issuing from the fimbriated end. The whole, except the left tube and ovary, was removed in one mass. Great difficulty was experienced in separating the cystic swelling from the deep part of the lateral wall of the vagina and surrounding tissues. The specimen showed the left horn to contain a normal cavity and cervical canal opening into the vagina. On the right side the large cavity, which contained altered blood, appeared to be a greatly distended cervical canal, above which was the enlarged right horn of the uterus with the haematosalpinx.

J. E. G. CALVERLEY, C.M.G., M.D., B.S.Lond.,
Surgeon,

J. W. D. BUTTERY, F.R.C.S.Ed.,
Assistant Surgeon,
Royal Victoria Hospital, Folkestone.

DRY FRACTURE OF NECK OF FEMUR.

I WAS particularly interested in Mr. Blundell Bankart's description (*Journal*, January 4th, p. 8) of a case of intracapsular fracture of the neck of the femur, in which he had obtained bony union after injection of blood into the hip-joint. I must admit that I was sceptical of the absolute absence of bleeding between the ends of the fracture and into the hip-joint, especially as I had often noticed an apparent fullness over Scarpa's triangle, and considered that it was due to effusion into the hip-joint. I wish, therefore, to place on record the following case, which showed a dry fracture of the neck of the femur investigated at necropsy.

W. M., aged 81, was admitted to the Radcliffe Infirmary with retention of urine and uræmic symptoms due to senile enlargement of the prostate. His retention was relieved by catheterization, but two days after admission he got out of bed one night and fell, breaking the neck of his femur. He was treated

palliatively by abduction and extension on a Thomas splint. He died five days after the fracture.

Extract from notes of the necropsy made by Dr. A. G. Gibson: "There is considerable bruising with the production of fair-sized blood clot in the muscles above and below the great trochanter. This bruising extends downwards to the distal third of the inner side of the thigh, possibly directed there by the sartorius muscle. The hip-joint was opened and contained no blood clot. A pipette passed to the back of the joint aspirated a few cubic centimetres of synovial fluid very faintly tinged with blood. There is a subcapital fracture of the neck of the femur, but neither surface of the fracture has any blood clot at all formed on it."

This case, with its marked bruising outside the joint, and absence of bleeding in the joint, gives some further definite evidence to encourage the injection of blood into the hip-joints of recent intracapsular fractures advocated by Mr. Blundell Bankart, with a view of obtaining bony union.

I have to thank Mr. Rose-Innes, under whose care this patient was, for permission to publish the case.

Assistant Surgeon, Radcliffe Infirmary and County Hospital, Oxford.

Reports of Societies.

INFLUENCE OF SUNLIGHT AND CLIMATE ON HEALTH.

At a meeting of the Section of Balneology and Climatology of the Royal Society of Medicine, on March 21st, with Dr. KERR PRINGLE in the chair, the influence of sunlight and other climatic factors, especially in the treatment of rheumatic disease, was discussed.

Dr. C. W. BUCKLEY said that the climate which seemed the most delightful was by no means necessarily the best adapted to the human organism. Barometric pressure, temperature, sunlight, rainfall, humidity, and prevailing winds were the chief factors which determined the character of climate. In this country, where grey skies were common, it was not surprising that great importance was attached to the record of hours of sunshine, and the longing of the Englishman in the Tropics for the grey skies of his native land was not always realized. The spells of sunny weather were too brief and broken to permit of acclimatization to the sun's rays in any degree. The results of research into the effects of light, both natural and artificial, were sometimes contradictory and unconvincing. They did not support the idea that natural resistance was increased to any extent by continual exposure to sunlight. The sun, while beneficial to the healthy, might be injurious to those suffering from severe infections, and, even in health, excess might produce undue fatigue. Wind was an important factor, and it had to be remembered that in the open the movement of air was as necessary as in closed rooms. Air movement played an important part in cooling action on the body, even if actually there was no change of air. High humidity was unfavourable, and changes in relative humidity as slight as 1 per cent. caused perceptible changes in the rate of evaporation from the skin. Rainfall was also an important factor. It had long been pointed out that heavy rainfall was an advantage from the point of view of health, clearing the air of impurities and probably rendering it more invigorating by favouring the formation of ozone and diminishing the relative humidity. It was the common experience of many people that they felt more fit for work during and after rain. The effect of these climatic factors was modified by the remarkable adaptability of the human organism. It was more advantageous to train the powers of adaptation to climate in treating rheumatism than to lower those powers by living in a warm climate. Newsholme had recorded that high incidence of rheumatic fever occurred when the mean temperature was high, the rainfall deficient, and the ground water level high. Recently the speaker had been investigating the incidence of rheumatic diseases among miners, who spent one-third of their lives underground, excluded from sunlight, in a warm and highly humid atmosphere. Among 1,496 cases diagnosed as various forms of rheumatism which had been under his care in the period 1926–29 at the Devonshire Hospital, Buxton, 452 were miners: they showed a high incidence of rheumatic fibrositis, but no higher than general outdoor workers exposed to cold and damp, with plenty of light. Miners had a lower incidence of infective arthritis and osteo-arthritis than many other classes of the community. It was a combination of conditions tending to lower the powers of adaptation which caused a high incidence of rheumatism, and not any single climatic factor. Dr. Buckley differed strongly from the popular view that if the climate of these islands were perpetual sunshine and the temperature variation not more than ten degrees the health of the nation would improve. A good case could be made out for the view that the British climate was the best of all possible climates for the average inhabitant of these islands.

Dr. W. P. KENNEDY (Bath) referred to the changing definition of rheumatic diseases. Formerly there were included in this category many conditions which had one by one been eliminated, and what remained was little more than a general ill health. He believed that some perversion of the metabolism produced the first irritation in the fibrous tissue which opened the way to the inroads of bacteria. Professor MEUZOT (Royat) said that many persons with chronic disease were worse on certain days, and it seemed as if the climate was implicated. In last September many cases of sudden death from cerebral haemorrhage or heart failure occurred in one small locality on one particular day. This was believed to have something to do with magnetic changes, and to be connected with the existence of black spots in the sun.

Dr. A. CAWADIAS said that chronic rheumatism was the result not of one but of many factors, external and constitutional. For every new patient these factors varied as to their number, intensity, and mode of combination. Each rheumatic patient had a special "etiological constellation," and in certain patients the climatic factor might be in the constellation as a star of the first magnitude and in others simply as a satellite. In Greece, where there was abundance of sunshine, there was much chronic rheumatism, though perhaps not so much as in Great Britain. To attribute rheumatism only to climate was one of those dogmatic simplifications of etiology for which there was no true foundation: in every patient a combination of factors was concerned. In the treatment of chronic rheumatism abroad he had for many years used the sun; coming to this country, where the sun was not so available, he started, with great scepticism, ultra-violet treatment, and was astonished to find that in his rheumatic patients it gave better results than the sun. He believed the reason to be that while people were accustomed to the luminous radiations, they were not accustomed to the short ultra-violet radiations, and these brought about a "shock" reaction which modified the metabolism.

Dr. GUSTAVE MOXON (Vichy) said that his experience in sending patients up mountains, to altitudes of 8,000 feet or so, was that the danger appeared when they came down again. On returning suddenly from high altitudes to the town they were very liable to catch any infection which was prevalent; their resistance was actually lowered by their stay in the mountains. In many cases they would derive far more benefit from ultra-violet treatment at home than from a stay at a high altitude. Professor FERREYROLLES (La Bourboule) said that patients differed greatly in their resistance to climate, and its effect in rheumatic cases was seemingly contradictory in many instances. The same thing was seen among patients with asthma; some were only well in cold weather, while others could not endure it. Dr. J. CAMPBELL MCCLURE said that excessive exposure to sunlight was harmful. Every autumn he had to treat a number of people for bronchitis and other complaints; these people during the summer had been exposing themselves, in abbreviated garments, to the rays of the sun, coming back with deeply pigmented skins to undergo a period of distinct depression. Rash exposure to the sun would often precipitate an attack among those disposed to bronchitis. Dr. P. G. LEWIS (Folkestone) remarked that in consequence of the fine summer of last year there had been distinctly less illness throughout the

country; sunlight had evidently a distinctly beneficial influence. He had been using ultra-violet radiation for two years, and in no instance had it failed to benefit the patient.

Dr. KERR PRINGLE, from the chair, said that some patients with rheumatism appeared to do better in a bracing climate, and others in a West Country climate. Residents in Harrogate, who ordinarily had a bracing climate, were unwise to go for their holidays to the East Coast, because this meant that they were kept at concert pitch all the year round; they should relax at a western station. A long time ago he was in charge of a home for waifs and strays on the North-East Coast: many of the children, in spite of abundance of sun and fresh air, did not thrive; when, however, they were sent far up the Tyne Valley into the middle of Northumberland they improved greatly.

THE THERAPEUTIC VALUE OF GOLD COMPOUNDS.

A MEETING of the Sections of Dermatology and Medicine of the Royal Society of Medicine, on March 20th, under the chairmanship of Dr. S. ERNEST DORE, was devoted to a discussion of the therapeutic value of gold compounds.

Professor S. L. CUMMINS said that sanocrysin (gold-sodium-thiosulphate), at first unduly vaunted as a cure or rashly condemned as a poison, was now gaining general favour as a useful adjunct to the treatment of tuberculosis. Whether it was to be described as a chemotherapeutic agent or not depended on whether the conception of chemotherapy was limited to that of Ehrlich; but it was undoubtedly a chemical substance with a selective action on tuberculous lesions, and capable of effective use in the treatment of tuberculosis. Its action, like that of other preparations of the heavy metals, appeared to be related to tuberculous foci rather than directly to tubercle bacilli; but the result of its skilled application in suitable cases was a tendency to improvement in regard to temperature, weight, and general condition, accompanied by a decrease in amount of sputum and number of tubercle bacilli excreted, so that sputum often became negative and might dry up altogether for the time being. This improvement appeared to depend upon an amelioration of the focal lesions, and the secondary destruction of many of the tubercle bacilli therein. The success of sanocrysin treatment depended thus upon the power of the patient to make use of the focal action of the gold salt, and it might be assumed that this power depended, in its turn, upon the degree to which the patient had learned to neutralize or to tolerate the toxic substances set free in the circulation through focal hyperaemia, as well as upon his phagocytic and bactericidal efficiency. This implied that the effects of any given dose of sanocrysin could not be uniform, but must necessarily vary according to the phase of tuberculosis in the individual patient. The art of sanocrysin therapy lay in the just appreciation of the patient's condition, and the regulation of dosage accordingly. Within the limits of the dose which could be given to a healthy person without the risk of metallic poisoning, the selection of the appropriate amount for the individual patient depended rather upon the laws which regulated vaccine therapy than on those which were applicable to drugs without a chemotherapeutic action. With the advent of heavy metal therapy in tuberculosis came the need for more scientific methods in the assessment of cases, and it seemed clear that in the near future a great deal of attention would have to be given to this aspect of the question. In the search for characters according to which cases might be evaluated and compared, it would be advisable to turn more and more towards ponderable and measurable changes than to those criteria which depended for their significance upon the individual skill and experience of the physician: among the surest guides were the temperature, the weight, and the amount, character, and bacillary content of the sputum. The great advances now being made in chest radiography, the recent progress in the study of blood changes in tuberculosis, and a better appreciation of the significance of tuberculin sensitivity afforded profitable lines along which future work might be directed in the assessment and comparison of cases before, during, and after treatment.

Dr. A. C. ROXBURGH and Dr. H. CORSI brought forward an account of more than forty cases, chiefly of lupus erythematosus, submitted to treatment with krysolgan or sanocrysin, and the results obtained. The krysolgan (sodium-amino-auro-mercapto-benzol-carbonate, with a gold content of approximately 50 per cent. by weight) was given in doses of 0.0015 to 1.5 grains, equalling 0.1 gram, intravenously. The sanocrysin, with a gold content approximately 40 per cent. by weight, was given in doses of 0.05 to 0.25 gram intravenously—that is, two and a half times the maximum dose of krysolgan and containing about twice the amount of gold. The intervals were one week between the smaller doses, and two weeks between the larger, and the average number of injections in each case was eleven with krysolgan and ten with sanocrysin. No local treatment was given during the injections except calamine lotion. Of the 35 cases of lupus erythematosus treated, 8 were cured temporarily, 6 very much improved; 9 were definitely and 2 slightly improved. There was no change in 5, and 5 patients became worse. Of the 8 "cured" cases 6 relapsed in a few months. The proportion of those improved to those not improved in the two groups was the same—namely, about two to one. Gold injections were also tried in 4 cases of Bazin's disease, with cure in one case, improvement in another, and no change in the remaining two. One case of papulo-necrotic tuberculides was improved, as was a case of erythrocyanosis frigida, and there was no change in a case of pityriasis lichenoides et varioliformis acuta. Toxic reactions, but none of them serious, followed 6 per cent. of the injections. The opinion of the authors of the paper was that there was little to choose between the two drugs. Any difference perhaps was in favour of sanocrysin, because it could be given in larger doses. The drugs were not a cure for lupus erythematosus, but a large proportion of cases improved.

Dr. C. J. MARSHALL said he had been using gold compounds since they were first tried and advocated in Copenhagen, and he had been impressed by the influence which the period of infection had upon the character of the reaction. His own clinical experience coincided with what Professor Cummins had found in his animal experimentation, that the best results ensued when the time elapsing between the onset of the infection and the treatment had allowed of the formation of local lesions. As sanocrysin was at first used on all kinds of tuberculous cases there were some lamentable results. He did not now use the gold compound less than a year from the commencement of the infection. He had not hesitated to give sanocrysin to a patient who was febrile when at rest, and in cases of this kind he had had good results. He was not aware of having been able to cure any tuberculous patient by means of gold compounds; in many patients, however, the symptoms had ceased after courses of treatment. Still, at some time a relapse occurred, more quickly in these cases than after the usual constitutional treatment. It was a fine achievement, however, to render patients fit to undergo constitutional treatment.

Dr. H. W. BARBER, who had treated a large number of cases of lupus erythematosus during the last few years with gold compounds, said that he first used krysolgan, then sanocrysin, and later still solgarnol, which had been reported to be less toxic as well as more efficacious than the other two. Almost always he commenced with very small doses and gradually increased them, but in the case of a resistant patient it might be worth while giving heroic doses. In all cases one must be sure that no lung tuberculosis existed. Some cases of tuberculide had responded well to the injection of gold preparations, but he did not claim to have cured them. He had seen more toxic reactions after sanocrysin than after the other gold compounds. One patient treated with solgarnol had developed a generalized lichenoid rash; that patient was already suffering from pulmonary tuberculosis. This treatment of lupus erythematosus was satisfactory up to a point; after it some of his patients had remained well for two or three years, but many had relapsed.

Dr. J. E. M. WIGLEY had treated twenty-one cases of lupus erythematosus with sanocrysin: none were worse for the treatment, and only one was unaffected by it, but in some the improvement was only temporary. Tests had indicated the presence of gold in the reacting skin. Dr. H. MACCORMAC spoke of the difficulty of determining whether cases of lupus erythematosus were tuberculous or not. There was an inherent difference in the conditions when treating lung lesions as compared with lesions of the skin. In the case of the lung there existed a whole focus surrounded by a tissue which was able to produce a reaction. In the case of the skin lesion, which was largely on the surface, half the possible reacting surface was cut off: that was one reason why there was more difficulty in getting results in these cases from drugs. He was interested in the point made by Professor Cummins that it was necessary to allow the tubercle bacilli to become fixed in the tissues and produce a reaction before the remedy could have effect; it was the same with syphilis. In two or three cases he had used sanocrysin for lupus vulgaris: definite improvement occurred, but not to the same extent as in lupus erythematosus. These compounds were a very valuable part of the dermatologist's treatment, clearing up cases which otherwise had proved very refractory. Dr. W. N. GOLDSMITH said that since 1925 he had treated every case of lupus erythematosus encountered by some gold preparation: gold injections were a great advance in the treatment of this hitherto intractable complaint. Most of his cases had reacted well, and some seemed to have remained cured at the end of three years after the treatment ceased. Though most of the cases of the disease relapsed, they again improved when gold injections were resumed. In consequence of his having learned of unfavourable results following sanocrysin injections, he had largely gone on to the use of krysolgan, triphal, and some of the other gold compounds which were on the market; metallic gold produced no effect. He very seldom gave a larger dose of triphal than 1.5 grams, the actual dose each time being graduated according to the response shown after the previous injection: if there were signs of a temporary reaction he diminished the dose. The compound which had the most rapid effect was triphal, and the only untoward effect was a slight and temporary malaise. At present there was no guidance as to the period during which treatment should be continued so as to prevent a relapse of the lupus erythematosus.

Professor CUMMINS, replying, said that some of the best results he had had from the gold treatment were in resting febrile cases. He had tried to insist that great caution must be observed in the matter of dosage in cases of that kind. If one limited oneself to the Secker technique, that sort of case would not be influenced by the treatment without causing shock. Sometimes these injections had an extraordinary effect on the temperature. The fact that Dr. Goldsmith found that these gold compounds acted better in the absence of a big lesion was interesting, but the speaker thought that in those cases there were microscopic hyperaemias present. Dr. CORSI also replied, mentioning that he had not used the heroic doses indicated by Dr. Barber; he would be somewhat anxious if that were done.

TREATMENT OF NEW GROWTHS OF THE PHARYNX AND LARYNX.

AT a meeting of the Section of Laryngology of the Royal Society of Medicine, on March 7th, Mr. R. R. SIMPSON reported a case of nasopharyngeal fibroma, in which the growth had been removed by diathermy, and exhibited instruments and a specimen.

The patient, a boy aged 16, had complained of nasal obstruction for one month, and an operation was performed after a preliminary high tracheotomy. The diathermy knife was introduced as for the removal of adenoids, but was moved in the reverse direction—namely, from below upwards, cutting slowly. The posterior nasal attachments were severed by the knife introduced intranasally.

Mr. CYRIL HORSFORD doubted whether the larynx was normal, since the right half was in continuous fixation, and there appeared to be a growth above it. Mr. TILLEY remarked that in parts of the country where no radium was available, diathermy provided a similarly bloodless method of treatment of new growths in this position. Mr. W. ROSE recommended diathermy as being the simplest and safest method available at present for dealing with these very difficult tumours. Mr. FITZGERALD POWELL said that Mr. Simpson's method seemed preferable to removal of the growth through the antrum. He had recently had a case of a sessile growth which could not be removed by the antrum, but it disappeared after radium treatment. Mr. MUSGRAVE WOODMAN thought it was very dangerous to use radium for the highly vascular sarcomas because of the subsequent rapid dissemination. Whenever it was possible he deemed it better to remove the tumour by diathermy, employing radium only to prevent recurrence.

Dr. DAN MCKENZIE showed a specimen of papilloma of the larynx, which had been removed from a boy, 8 years of age, by the indirect method. He said that the risk of using cocaine in children has led to the trial of a 5 per cent. solution of stovaine in water, with a few drops of adrenaline, satisfactory anaesthesia being thus obtained. In this case, however, the successful outcome was chiefly due to the exemplary coolness of the patient.

Sir STCLAIR THOMSON thought the use of cocaine in the nose of children was very dangerous unless it was carefully localized; it was less risky in the pharynx. Dr. P. WATSON-WILLIAMS disagreed with this conclusion, since he had found cocaine quite safe for patients under the age of puberty; it should, however, be always used with great caution. Sir JAMES DUNDAS-GRANT concurred as regards the danger of sprayed cocaine in children, and said that it should be applied on cotton-wool. Dr. DAN MCKENZIE mentioned that the worst cases of cocaine poisoning he had seen had been in children and young people; it should not be used without adrenaline.

Mr. ARCHER RYLAND showed a patient, aged 48, with intrinsic carcinoma of the larynx treated by radium. There was a history of hoarseness of gradual onset, which had lasted six months, and the left vocal chord was found to be the seat of a neoplasm with a suspicion of subglottic extension. Microscopical section revealed that it was a typical squamous epithelioma. A window resection of the thyroid ala was performed, and seven needles, each containing 1 mg. of radium element, screened by 5 mm. platinum, were placed upon the deep perichondrium and secured in position. The radium was left in for seven days and a total dose of 1.176 mg. hours was administered. A prophylactic exposure of the tracheal wall was associated with the operation, but the insertion of a tracheotomy tube did not become necessary.

Osteomyelitis of the Cranium.

Dr. DAN MCKENZIE showed skiagrams of a skull after excision of bone for spreading osteomyelitis. The patient was operated on in 1926, and the skiagrams had been taken a month ago in order to determine whether regeneration of bone had occurred. Dr. LOGAN TURNER referred to a case which had been reported by Dr. MacLean of Newcastle, in which the left half of the frontal bone had been removed for spreading osteomyelitis. Three months later there was only a small area of disease, the size of a florin, where the dura mater was exposed; all the rest of the bone had regenerated.

Mr. VLASTO showed a case of chronic osteomyelitis of the frontal sinus and ethmoidal cells in a boy aged 16.

The patient was first seen in April, 1923, seven weeks after an abscess had been opened. On examination a suppurating wound was found in the region of the left frontal sinus, from which granulations were sprouting. Dead bone could be felt with a probe at the bottom of the wound: there was a considerable amount of proptosis, with slight limitation in movement of the left eye. Pus and granulation tissue occupied the left nasal fossa. The patient looked ill, but there were no constitutional signs. A week later the left frontal sinus and ethmoidal region were exposed through the usual incision, revealing extensive disease of the floor of the sinus and of the ethmoidal cells.

In the light of after events it seemed obvious that the operative removal had not been sufficiently radical, and that a mistake had been made in closing the external wound and draining entirely through the nose. After this treatment, however, the proptosis considerably diminished, but pus continued to exude externally through a sinus and into the nose. In the middle of June, 1923, the scar was reopened and more diseased cells and granulation tissue were removed. The possibility of malignancy was considered, but the material reported upon later was purely

inflammatory. The sinus had nearly healed at the beginning of July, but the presence of pus in the nasal fossa rendered it likely that the inflammatory process was not at an end. In November, 1928, the wound was reopened and a diverticulum of the upper and inner frontal sinus was found filled with granulation tissue. More diseased bone was removed, and, for the first time, the external wound was left widely open, being packed with iodoform gauze. For fifteen months afterwards the patient's local condition remained much improved, but there was still some pus in the nose and a very small sinus. Treatment consisted in frequent irrigation of the frontal sinus through the breach in the outer wall of the nasal fossa. In January, 1930, the wound was again reopened and the disease freely removed from outside and from within the nose. The diseased area seemed to be most marked over the partition between the right and left frontal sinuses. The boy's condition at present was a little better than it had been before the last operation.

CAESAREAN HYSTERECTOMY.

A MEETING of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on February 14th, with the president, Professor A. H. DAVIDSON, in the chair. Dr. BETHEL SOLOMONS read a paper on Caesarean hysterectomy, which appears at page 584.

Dr. D. G. MADILL, who opened the subsequent discussion, referred to the relative merits of bougies and the stomach tube. He mentioned that in cases in which he had to induce labour he always used a stomach tube; he had never been unsuccessful when employing this means, though with bougies he had repeatedly failed. Dr. J. S. QUIN reported a case of accidental haemorrhage following the insertion of a stomach tube; there had been absolutely no bleeding at the time the tube was inserted. He regretted that there was no infallible method of inducing labour. Dr. T. M. HEALY thought that Caesarean hysterectomy added nothing to the difficulties of Caesarean section or the time taken by it. As regards the question of craniotomy versus hysterectomy he expressed the belief that the latter was safer and easier than a difficult craniotomy. In some cases of fibroids he preferred to perform Caesarean section and to remove the fibroids at a later period.

Professor D. V. MORRIS said that in coitional sepsis the presence of plasma cells suggested that the condition might have been one of chronic sepsis which had lighted up, apart altogether from the insertion of bougies. He cited the case of a patient who previously had had an operation for backward displacement. She had pains for two hours, but had made very little progress considering she had had six children previously without any difficulty. It was thought that Caesarean hysterectomy was indicated, and this was performed. The whole pelvis was a mass of adhesions, there was marked evidence of oedema of the uterine wall, and sepsis occurred afterwards, though at the time of the operation there did not seem to be any reason whatsoever for sepsis. Dr. N. FALKINER considered that Caesarean hysterectomy was indicated in cases of cardiac decompensation. He had tried it recently, and the case had done particularly well. He thought that by this means the danger of sepsis occurring in the puerperium was obviated. Dr. R. M. CORBET thought it should be employed more frequently in cases of rupture of the uterus. He had seen eighteen cases of this condition, eight of which had been treated by hysterectomy; only one patient had died. If it was possible to make a definite diagnosis of rupture of the uterus before the child was delivered, it might be justifiable in such a case to open the abdomen and perform Caesarean hysterectomy. This, of course, was only possible if the patient was in hospital, or lived close to a hospital, and could be sent there quickly. He had seen a number of patients plugged before hysterectomy, and thought that convalescence was delayed thereby.

Dr. BETHEL SOLOMONS, replying, said he did not like the tube method of inducing labour. He had probably been unfortunate in seeing haemorrhage following its introduction, but he had always thought that it displaced the presenting part and might cause prolapse of the cord. He believed also that the introduction of three or four thin instruments like bougies was safer than the insertion of a bulgy apparatus like a tube. The bougies must not be blamed for the sepsis in the case reported: the husband was blameworthy. He referred to the excellent report just issued by Dame McIlroy from the Royal Free Hospital; there was mention of three deaths having occurred in cases where the tube had been used. Sometimes hysterectomy added to the danger of Caesarean section, although the operation was possibly simpler to perform. The ethical side of the subject appealed to him; he had found it entirely unnecessary to remove the uterus when section was employed in a case where craniotomy might have been indicated. In this class of case the lower segment section operation followed by drainage was uniformly successful. As mentioned in his paper, the ideal treatment for fibroids in pregnancy was to leave them alone; otherwise, myomectomy should be performed.

TOXIC GOITRE.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on February 28th, with the president, Mr. R. ATKINSON STONEY in the chair, Sir WILLIAM I. DE COURCY WHEELER showed an anaesthetic screen for thyroidectomy, and Mr. T. P. DUNHILL of St. Bartholomew's Hospital read a paper on toxic goitre, illustrated by lantern slides.

Mr. Dunhill said that the differences in the manifestations of toxic goitre in different patients were so obvious as to suggest two diseases: the so-called exophthalmic goitre, with staring eyes, pronounced nervous symptoms, and rapid but regular heart rhythm, being most common in early adult life; and the so-called toxic adenoma, rarely associated with exophthalmos, with comparatively mild nervous symptoms but an irregular heart rhythm, occurring on an average two decades later than the onset of exophthalmic goitre. The difference between the groups was probably one of degree only and not of kind. A full range of cases existed, representing every stage between exophthalmic goitre at one end and toxic adenoma at the other; a graded series of cases revealed exophthalmos and nervous symptoms becoming less and less until they almost or entirely disappeared. Corresponding with this the thyroid gland was found to become less smooth and more nodular, until the stage was reached of a gland with a single adenomatous mass. Toxic goitre was therefore one single disease, the manifestations of which differed under varying conditions: these conditions depended upon the following etiological factors. (1) *The stimuli.* There was evidence that normal stimuli could become excessive and therefore abnormal, and that these abnormal stimuli affected the thyroid gland detrimentally. (2) *The gland.* A patient might have a gland which was normal, or a gland which had already become a colloid goitre, or which had passed through stages of hyperplasia and involution and become a nodular goitre, or an otherwise normal gland containing an adenoma. These changes were frequently occurring apart from toxicity, and on to a gland in any one or any combination of these states there might be directed the pathological stimuli which constitute the first factor. (3) *The body cells*—for example, the muscle fibres of the heart, an organ influenced by thyroid secretion to a measurable extent; this factor of the heart before it was affected might also vary within wide limits. Surgical treatment must not be rigidly standardized, and must vary according to the clinical condition when the surgeon's advice was first sought. If the case was primary, no operation was performed in the earlier months. Septic foci were removed, adequate rest was given, and small doses of iodine were administered. If the patient did not improve, an operation was considered. If the disease was of the secondary type, nothing was gained by delay, and an operation should be performed as soon as the patient had been sufficiently prepared. Regarding the extent of operation required, it was essential to remove a sufficient amount of the second lobe. A less extensive operation, even the ligature of an artery, might give surprisingly good temporary results, but these were hardly ever permanent. No one should be induced to operate upon a patient until her assurance had been received that she would permit the completion, in stages, of what might be necessary. In patients who were

very ill, it was wise to tie the vessels at a preliminary operation, and, even then, to remove one lobe first.

The PRESIDENT remarked that, *although Mr. Dunhill* doubted the existence of any basic difference between exophthalmic goitre and toxic adenoma, in Dublin a great number of cases of toxic adenoma were not seen. In Ireland there were not so many cases of goitre associated with toxic symptoms but without exophthalmos as there were in other places. Until comparatively recently, such cases had been considered the property of the physician, and surgeons had not had much opportunity of operating on them. As regards preliminary ligation Plummer had stated that the introduction of iodine treatment had completely done away with the necessity for this. With reference to *x*-ray complications he mentioned a recent case; the patient had had no medical treatment whatsoever, but it had been one of the most difficult cases he had ever operated on, the tissues being matted together. He thought it possible, therefore, that in some cases the physician and radiologist were blamed for the matting of tissues which was not really their fault. Mr. W. PEARSON did not agree as to the rarity of cases of toxic adenoma; Mr. Dunhill had cleared up the pathological obscurity of these cases. Ligation was sometimes extraordinarily good in its results; the speaker had performed this in one case many years ago, and the patient had remained perfectly well ever since. Sir WILLIAM TAYLOR believed that the number of cases of primary toxic goitre seen in Ireland was considerable, but secondary toxic goitre associated with adenomatous changes was more rare. He had never seen a case of primary toxic goitre in which a preliminary ligation had been required, and he had been told by Plummer that when these cases were treated with rest and iodine, preliminary ligation was unnecessary.

Sir WILLIAM WHEELER said that the patient with toxic goitre necessitated co-operation and team work between the physician, surgeon, and biochemist. In Dublin the incidence of the disease was high; the troubled years through which the country had passed, and the mental strain to which individuals had been subjected, accounted probably for the large number of cases. Kocher was the great surgical pioneer of this work, and the speaker had, about twenty-five years ago, spent three months in his clinic. The surgery of Graves's disease was, at that time, practically unknown in these countries. The results in the hands of so great a master were most impressive. Notwithstanding the admirable effects of Lugol's solution, it was sometimes necessary to perform operation in carefully planned stages. In his experience the cases with marked mental disturbance were the gravest of all surgical risks. There were very few contraindications to operation. Patients with mania or with general anasarca should be given the benefit of multiple-stage operations. Cases of diabetes and pregnancy could be operated upon after careful preparation without much increased risk. He only operated on cases in which careful medical treatment had been tried and had failed, but he pleaded for surgical intervention before complications supervened.

Mr. H. MEADE stated that, although he had recently seen numerous cases of toxic adenoma, five years ago he hardly ever encountered a case. He thought that if these cases were really numerous more cases of the primary type would be seen. He had found that previous *x*-ray treatment added time and difficulty to the operation. Dr. R. STURPF believed that deep *x*-ray application could be of great help in diminishing the operative risk, and that the most favourable cases for treatment were those of acute and subacute exophthalmic goitre. He thought the fact that in many cases numerous exposures of superficial *x* rays were given without much effect was responsible for the impression that deep *x* rays were not helpful. Dr. LEONARD ABRAHAMSON considered that Mr. Dunhill's views accorded much more with observed facts than the arbitrary classification propounded by Plummer. In his experience there was a very high incidence of goitre of all types in Ireland, while primary toxic goitre had increased in frequency since the troubled times. Where simple goitre persisted in spite of treatment operation should be advised, since it was quite illogical to defer operation in a case of simple goitre, even where adenomata could not be felt, until toxic symptoms supervened. In the treatment of primary ("exophthalmic") goitre, he stressed the importance of mental rest and quietness.

Mr. D. KENNEDY mentioned a paper which he had written on the safety of operation in cases of toxic goitre. He had no doubt that *x*-ray treatment made operation more difficult, if not more dangerous. Mr. F. J. MORRIN said that in all cases of toxic adenoma he gave iodine as a pre-operative measure. He mentioned a patient who had been treated by *x* rays for many years, and whose neck was now infiltrated to a considerable extent; he did not think an operation scar would have been more disfiguring. He believed that primary *x*-ray treatment rendered operation much more difficult, but he had seen great improvement follow ligation of the superior arteries. He had not been impressed by the use of local anaesthesia; in fact, he thought that in many cases it was very undesirable. The ideal anaesthetic was avertin, but it was essential to give the maximum amount. He asked if Mr Dunhill left the isthmus, and thought that by doing so the post-operative distress was greatly lessened.

Mr. DUNHILL, in reply, said that if rest was made too rigid it could defeat its own end. Co-operation should always exist between the surgeon, physician, and radiologist. *X*-ray treatment did good in many cases, particularly if the patient was young and was treated in an early stage; in some cases it rendered the operation more difficult, but in others it did not. Iodine was particularly useful in cases of secondary toxic goitre. Avertin was good, particularly for young people whose hearts were strong and lungs clear, but it was extremely dangerous in cases of fibrillation with congestive heart failure. He never left the isthmus when operating.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of the Aberdeen Medico-Chirurgical Society was held on March 6th, with the president, DR. CHARLES FORBES, in the chair. Mr. F. K. SMITH demonstrated a case of osteitis fibrosa cystica of the right femur in a girl aged 18. Slight injury to the right thigh at the age of 7 had been followed by confinement to bed for a year; some shortening of the right leg had later disappeared. When 10 years old she had again fallen and fractured the thigh; recovery was good and there was no immediate limp, but gradually shortening was noticed, with prominence of the thigh and swelling of the shin. The patient had been admitted to hospital a month previously with pain in the right thigh, and *x*-ray examination showed the presence of typical fibrocystic disease of the neck and nearly the whole shaft of the right femur. The bone was fractured at the junction of the upper and middle thirds. The tibia and fibula of the same side also showed fibrocystic change, but no other bones were affected. The remarkable points in the case were the long duration of the disease, the earlier injuries having been pathological fractures, and the widespread involvement of the shaft of the femur. Mr. Smith also showed a case of syringomyelia of long standing in an engine driver aged 48. The initial symptom, a sense of tingling in the neck, had occurred twenty-five years previously. Three years later the skin of the right forefinger had peeled off like a glove. At the present time the patient complained of pain and stiffness about the right shoulder; his fingers blistered easily, and took long to heal. There was swelling of the right shoulder, forearm, and wrist, with dilated veins on the upper arm. Pain and thermal sensation were lost over the right arm, and the right side of the chest, neck, and face. The Wassermann reaction was negative and the cerebro-spinal fluid normal. The Romberg sign was negative and all reflexes were normal. Ocular examination revealed nothing abnormal and the muscles of the right arm reacted normally to electrical stimulation. The radiograms of the shoulder and wrist were almost typically those of Charcot's disease. The lesion was localized as stretching from the level of the second cervical to the sixth thoracic segment.

Dr. A. GREIG ANDERSON pointed out the salient features in a case of gross myxoedema in a married woman aged 37.

The countenance could almost be described as alabaster with malar flush. The hair was lustreless, the eyebrows scanty, the skin dry and crusty, and the expression vacant. The tongue and lips were thick and the voice hoarse. There was supraclavicular padding, and enlargement of the hands and feet. The patient was lethargic, mentally confused, and had delusions at night. The basal metabolic rate was *minus* 18 per cent., and the cholesterol content of the blood was increased, 228 mg. per cent. There was no albumin in the urine; a fractional test meal showed the presence of a large amount of mucus in the stomach contents. The patient had commenced treatment with thyroid extract.

Dr. A. W. HENDRY brought a case of mediastinal tumour. The illness had commenced on June 1st, 1929, with cough, dyspnoea, and pain in the right chest. On admission to hospital on June 14th, fluid was found in the right pleural cavity. No glands were discovered. X-ray examination showed the presence of a large tumour of the posterior mediastinum. Dyspnoea became more marked and cyanosis supervened with turgidity of the veins of the neck and arms. Deep *x*-ray therapy was commenced with dosage at fortnightly intervals, with amelioration of symptoms and disappearance of the dyspnoea and cyanosis. There were now some enlarged glands in the neck, but the patient felt so well as to wish to return to work.

Dr. GEORGE SWAPP demonstrated a case of carcinomatosis in a woman aged 68. An ulcerative condition of the left breast had existed for thirty years; this had at first been thought to be tuberculous mastitis since there was a strong family history of tuberculosis. In 1928 small nodules had begun to appear round the ulcer and to ulcerate; they had been treated with brilliant green, and healing had followed. The ribs, sternum, scapulae, vertebrae, and pelvis now showed metastatic deposits, and the skin metastases were spreading to the abdominal wall. Secondary deposits were present in the lung and had been treated with deep *x*-ray therapy. Dr. Swapp also outlined the symptomatology and treatment of spasmodic torticollis, and showed a case in a woman, aged 30, who had been cured by operation after treatment by sedatives, alcohol injection, and cervical support had failed. The posterior primary branches of the second, third, fourth, and fifth cervical nerves on the right side had been excised under intratracheal anaesthesia. The indications for operation in such cases were persistence of spasm and severe insomnia, difficulty in deglutition and respiration, and profound mental depression.

FRACTURES INVOLVING THE KNEE-JOINT.

THE Manchester Medical Society held a joint meeting with the Liverpool Medical Institution, on March 5th, at the University of Manchester, when Professor ALBERT RAMSBOTTOM, president of the Medical Society, was in the chair. Mr. R. WATSON JONES (Liverpool) read a paper on the treatment of fractures involving the knee-joint.

Mr. Watson Jones arranged the 160 knee-joint fractures on which his paper was based in three groups: (1) fractures involving the extensor apparatus, where the problem of treatment was to restore full extensor power without impairing flexion movement; (2) fractures involving the weight-bearing areas, where the problem was to restore stability and prevent osteo-arthritis; and (3) fractures producing internal derangement of the joint. The first group included fractures of the patella. The questions whether operation was essential, whether the bone should be sutured or merely the capsule, which suture material should be used, and when movements should be commenced, were answered by showing that perfect results demanded sufficiently firm operative fixation to allow early movement. Catgut, kangaroo tendon, and silver wire were all fragile, and the speaker advocated a suture of twisted braided silk, which was eventually converted into living fibrous tissue, introduced in the form of a square stitch through the bone. This not only prevented separation, but controlled tilting of the fragments on each other. Fascia lata was only used for avulsion of the ligamentum patellae, and was valuable here because the normal attachment of the ilio-tibial band to the tibia was utilized in anchoring the patella. It was notoriously difficult to stitch the vertical fibres of the ligament to a bare area of the patella held upwards by the tension of the quadriceps; the technique described overcame these difficulties and rendered the operation easy. Cases of avulsion of the quadriceps were shown, and the relationship to "myositis ossificans of the quadriceps" discussed. The treatment of displacement of the epiphysis of the tibial tubercle depended on the age of the patient. If the fragment had fused with the upper tibial epiphysis, displacement was limited and non-operative methods adequate; but if it was still free, the marked upward displacement of the small fragment demanded operative treatment.

The second group included linear fractures of the femoral condyles and tibial tuberosities, where treatment was relatively simple, and comminuted compression fractures of the outer tibial tuberosity, where treatment was difficult. This fracture was produced by the splitting action of the outer edge of the outer femoral condyle, brought into contact with the tibial plateau in severe valgus deformity of the knee, so that preliminary rupture of the lateral and crucial ligaments and simultaneous splitting of the outer semilunar cartilage were inevitable. The objective of a stable joint free from arthritis demanded operative treatment, with sufficiently long immobilization for repair of the crucial ligaments; the practice of early movement in this injury was condemned. Cases were shown of totally disorganized knee-joints, reconstructed so that the patients had returned to full work. In an age of reconstructive surgery the temptation to choose the easy path of arthrodesis was to be avoided. The treatment of displacement of the lower femoral epiphysis was illustrated by typical cases, by a case occurring with subperiosteal haemorrhages in scurvy, where the displacement was pathological and not traumatic, and by a case of a day-old baby, where the displacement was a birth injury.

In the last group fractures of the tibial spine and detachment of articular fragments were discussed. The forward displacement of the tibial spine was due to the pull of the crucial ligament, and to the elastic recoil of the outer semilunar cartilage, but operative replacement of the detached fragment after division of the anterior horn of the cartilage was not always required. Illustrative cases were demonstrated. A previously undescribed condition was shown, where the styloid process of the fibula had been displaced into the knee-joint. The fragment had been torn off by a varus strain of the knee, and, with the biceps tendon and lateral ligament still attached, it had been imprisoned between the joint surfaces as they sprang together again. The complication of external popliteal palsy completed a remarkable resemblance to the injury recently discussed in the literature, of displacement of the internal epicondylar epiphysis of the humerus into the subluxated elbow-joint with ulnar palsy.

Cutaneous Anthrax.

Dr. A. E. HODGSON of Liverpool read a paper on cutaneous anthrax, based on the clinical observation of 45 cases which had been treated with anthrax serum and local applications of eusol fomentations, without recourse to excision of the infected area. There were four fatal cases; the patients were infected in or near the anterior triangle of the neck, and died within four to eighty hours after arrival at hospital for treatment. The speaker said that the clinical and bacteriological diagnosis in typical cases was moderately easy, but in others it might be difficult, since the anthrax bacillus might be present in extremely small numbers. Anthrax serum was given daily, intravenously, in doses of 100 c.cm. or more, as the clinical signs might require. In the series the largest total dose was 1,100 c.cm. and the smallest 90 c.cm. Locally, hot eusol fomentations were frequently applied until the inflammation abated. In doubtful cases a small dose, such as 20 c.cm., should be injected intramuscularly, pending definite diagnosis. Swabs from the wound were usually negative in a fortnight or so. The prognosis was good, provided that the treatment was commenced within two, or at the most three, days, except in anterior cervical infection, in which profound toxaemia, with great liability to fatal syncope, and oedema of the glottis rapidly arose.

Post-anaesthetic Vomiting.

Dr. G. F. RAWDON SMITH of Liverpool read a paper on post-anaesthetic vomiting, in which he referred to an investigation of the acid intoxication problem, particularly in regard to disturbances of the pancreatic function. The results of observations made during the past ten years at the Liverpool Hospital for Women in regard to post-anaesthetic sickness were described. It was shown that the particular brand of ether had little or no effect; that modifications of the generally accepted preliminary hypodermic medication were usually disappointing; that the use of carbon dioxide in any quantity was liable to be followed by excessive vomiting; and that insulin and glucose were most valuable in the prevention and treatment of post-anaesthetic toxaemia.

PROGRESS IN STREPTOCOCCAL RESEARCH.

A MEETING of the Pathological Society of Manchester was held on March 12th, when Dr. A. W. DOWNIE read a paper entitled "Recent work on streptococci."

Dr. Downie began by reviewing recent studies of the toxins of haemolytic streptococci, with particular reference to scarlet fever. Before the work of the Dicks the view was held by some observers that scarlet fever was a local streptococcal infection of the throat, and that the general symptoms were due to a diffusible toxin produced by these organisms. This view was not, however, generally accepted until more direct evidence was obtained by experiments on man. A notable advance in the state of our knowledge was made by the Dicks, who produced scarlet fever in human volunteers by swabbing their throats with pure cultures of haemolytic streptococci. They demonstrated also the production of toxins by means of skin tests in susceptible individuals. Further work on the production of antitoxic serums in horses, on the effect of such serums in the treatment of scarlet fever, and on the results of active immunization by injections of toxin, afforded additional support of the view that scarlet fever was primarily a streptococcal infection. While scarlet fever antitoxin had proved to be a valuable therapeutic measure, when used during the acute stage of the disease, the reports of various observers seemed to indicate that it was much less efficacious in the treatment of septic complications. Moreover, the reports published by Kinloch, Smith, Taylor, and others, and the experimental work of Parish and Okell, indicated that antitoxin immunity apparently did not prevent the occurrence of local streptococcal infection. It had been found that toxins apparently similar to those obtained from cultures of scarlatinal streptococci were produced by haemolytic streptococci from other human infections, such as erysipelas, puerperal fever, and cellulitis. While some of the published work would seem to show that the toxins of erysipelas and puerperal fever differed immunologically from those of scarlet fever, the evidence seemed to be in favour of the view that they were identical, and could be neutralized by scarlet fever antitoxin. The difference between the toxigenic properties of scarlatinal organisms and those from other sources would seem to be quantitative rather than qualitative. Recent studies on puerperal sepsis in relation to antitoxic immunity as indicated by the Dick test, however, did not suggest an exact correlation between such immunity and the immunity to streptococcal infection during the puerperium. Further, the cases recorded recently by Burt-White did not indicate that the treatment of puerperal septicaemia by scarlatinal antitoxin yielded highly satisfactory results. In streptococcal infections, other than scarlet fever, it could hardly be expected that the results of treatment with antitoxic serums would be so good as in that disease, because all virulent streptococci of the haemolytic group had not been shown to produce toxin; toxin of the skin-reacting type was not the only means by which streptococci exerted their pathogenic effects. In immunity to haemolytic streptococci there would seem to be two factors to be considered—antitoxic immunity and antibacterial immunity. Dr. Downie described some results of his own experimental work on animals, bearing on these problems and on the nature of immunity to haemolytic streptococci.

Reviews.

ANAESTHESIA AND ANAESTHETICS.

IN their textbook on *Anaesthesia and Anaesthetics*[1] Drs. ROOD and WEBBER adopt the somewhat unconventional plan of incorporating a description and discussion of the problems presented by the physiology of anaesthesia in the fabric of their work, considering each individual problem as it arises in the text, instead of following the general practice and devoting a separate chapter to the whole subject. The method has obvious disadvantages. On the other hand, by presenting the academic aspects of the subject in relation to their practical application it is more likely to engage the student's interest than the highly technical chapter on the physiology of anaesthesia to be found in most textbooks.

The work, which represents the teaching of the school to which the authors belong—University College Hospital—is intended mainly for the non-specialist reader; but even to those who have read many textbooks it offers much valuable information and wise counsel. Indeed, we cannot help thinking that the book would appeal even more to those who have some knowledge of anaesthesia and its technique than to the student confronted with the subject for the first time. Generally speaking, to the latter a more formal textbook is better suited unless he has been very well grounded in the subject by preliminary lectures. Undoubtedly to the student already equipped with some knowledge of anaesthetics the book will prove very useful, for its material is obviously derived from the authors' personal experience and presented in an extremely interesting manner. They hold the balance justly between the old anaesthetics and methods of administration and the new; they do not discard the former because they are no longer fashionable, or laud the latter unless there is good reason.

It is a common error to condemn drugs or methods of administration when the fault lies rather with the anaesthetist who has applied them unsuitably. No one anaesthetic or method is ideal in every case; the best results can be obtained only by those who are skilled in the choice of a suitable anaesthetic, in the method of administration appropriate to each patient, and in the early recognition and treatment of the emergencies that may arise in the course of anaesthesia. This book should help students to attain such a high standard of efficiency; it may be recommended not only to them, but to the general practitioner who in the course of his work gives an occasional anaesthetic. The publishers have done their work well, and both the type and the illustrations are excellent.

HUMAN HELMINTHOLOGY.

A NEW book on *Human Helminthology*,[2] by ERNEST CARROLL FAUST, has recently been published. It contains an account of all species of worms which have been recorded from man, including forms like the extremely rare free-living hair worms (Gordiacea) and the thorny-headed worms (Acanthocephala); and the pathogenicity, symptomatology, diagnosis, prognosis, and therapeusis of each species is dealt with. There are, in addition, chapters on parasitism, the relationship between the parasite and its host, a historical account of the development of helminthology, and a further chapter dealing with the geographical distribution of helminth parasites. The book also contains a brief description of the intermediate and reservoir hosts—arthropod, crustacean, and plant—concerned in the distribution of these worm infections, together with instructions on methods of examining these hosts for parasites. Laboratory methods are very adequately dealt with. The equipment necessary, the collection, preparation, and preservation of material, and the identification and differential

[1] *Anaesthesia and Anaesthetics.* By F. S. Rood, M.B., B.S.Dunelm, and H. S. Webber, B.Chir.Cantab. London: Cassell and Co., Ltd. 1930. (Demy 8vo, pp. xi+292; 56 figures, 4 plates. 15s. net.)

[2] *Human Helminthology.* By Ernest Carroll Faust, Ph.D. London: H. Kimpton. 1930. (6 × 9¼, pp. xxii + 615; 237 figures. 35s. net.)

diagnosis of parasitic worms and their eggs are discussed in great detail. A very useful chapter dealing with scientific nomenclature is added. The book comprises 616 pages and contains 297 illustrations. With the exception of a few photomicrographs the figures are excellent.

In the trematoda the commonly accepted scheme of classification, based as it is largely on the morphology of the adult, is considerably modified, great stress being laid on the importance of the excretory system of the cercariae and adult, and especially of the first-named. Formulas relating to this system in the miracidia and cercariae are included in the definition of some of the suborders and superfamilies, but the characters of the genera dealt with are not defined. Adult worms are referred to as maritae, metacercariae as adolescariae, and the sporocysts and rediae as parthenetic generations. These terms will be new to English students, but they are defined. As the author rightly points out, "the excretory system can be studied satisfactorily only in the living material, and then only in species sufficiently transparent to permit the investigator to observe the various parts of the system in a fluke compressed under a microscope cover-glass." It will therefore be clear that the value of the excretory cells from the classification point of view is very limited, and especially is such the case with medical and veterinary students, who are, for the most part, concerned primarily with the accurate diagnosis of helminthic infections in man and animals. It remains to be seen whether the classification based on the nature of the excretory system is more constant and reliable than that accepted up to the present by other helminthologists. The general description of the trematode worms is admirable, and especially so in the case of the schistosomes. The account of the cestoda is very well done, and contains all that the student requires for the diagnosis of tapeworm infections. Helminthologists will, however, probably not agree with the author's limitation of the genus Dibothriocephalus to species which, in the adult stage, occur in fish, or to the similar restriction of species of the genus Diphyllobothrium, to those adults of which only the larval stages occur in fish. The descriptions of the nematode parasites are very full, clear, and up to date, the hookworms and filariidae being especially well done. At the end of the volume there is a very long and elaborate diagnostic key for the "identification of adult worms and larvae in advanced stages of development." Keys are often very useful, but here the field is so vast and the species so varied that diagnostic characters cannot be satisfactorily embodied in a key.

The author has a wide and a practical knowledge of the subject, and has had considerable experience in teaching. From a student's point of view, however, it is perhaps a little unfortunate that a greater distinction is not made between the commoner and the rarer parasites. Dr. Faust rightly points out that he "has depended on the work of his colleagues for much of the evidence and many of the views expressed"; the same remark applies equally well to many of the illustrations reproduced. Generally speaking, the book is excellent, and can be recommended with confidence to all who wish to take up the study of human helminthology, and to teachers who desire to have a handy book for ready reference.

CLINICAL ATLAS OF BLOOD DISEASES.

IN their vade-mecum for haematologists[3] Drs. A. PINEY and S. WYARD have compressed into less than a hundred pages most of the information needed for the rough diagnosis of blood diseases from blood films; though, of course, haematologists cannot live by dried films alone. The book is intended chiefly for the use of the practitioner, and it may be helpful to those who have time to attend to the clinical pathology of their cases, and who are already familiar with haematological technique; possibly also it may be useful in clinical laboratories. Besides the very concise, perhaps too concise, account of a number of clinical states, some of which cannot really be regarded as blood diseases, the feature of this book is the coloured plates which represent with fair accuracy the appearances of the stained cells met with in the blood of these diseases. The films from which the pictures have been prepared are stated to be all stained by Jenner-Giemsa method; they are, however, not uniformly stained (compare the pictures of polymorphonuclear leucocytes in plates 21, 22, and 24). Plates 14 and 19, showing reticulocytes, are certainly drawn from films which had been stained by some other process. This is unfortunate, and may easily betray into serious error the practitioner who relies on blood films for diagnosis. The eosinophil cell in plate 5 is noted as being stained by Jenner (p. 8), but the picture is not very accurate; the nuclei of Jenner-stained eosinophil cells stain pure methylene blue and have no red or violet tint, and the granules are pinker and coarser. Readers will be grateful for the admirable glossary of haematological terms which so often make a stumbling-block for the inexperienced worker. A regular index would, we think, be more useful than a table of contents. The text is remarkably free from misprints, but we note on page 68 "myeblasts" for myeloblasts. The publishers are to be congratulated upon the production of so comprehensive a book at the moderate price of 12s. 6d.

[3] *Clinical Atlas of Blood Diseases.* By A. Piney, M.D., M.R.C.P., and Stanley Wyard, M.D., M.R.C.P. Churchill's Empire Series. London: J. and A. Churchill. 1930. (5¼ × 8¼, pp. xv + 98; 36 plates. 12s. 6d. net.)

"ANNALS OF MEDICAL HISTORY."[4]

THE concluding instalment of the first volume of the new series of the *Annals of Medical History*, now a bimonthly instead of a quarterly publication, opens with the first William Snow Miller Lecture, given by Professor T. Wingate Todd of Cleveland, in March, 1928, at the University of Wisconsin on "The medieval physician," which pleasantly touches on Salerno and Padua, and on Paracelsus and other men of old time. Dr. Harry Friedenwald contributes a learned and beautifully illustrated account of the manuscript medical works of Isaac Judaeus in the ninth century, and on the diploma of Copilius Pictor or Koppel Mehler, a Jewish graduate of Padua in 1695. The activities of Hieronymus Brunschwig (1450–1533) of Strasbourg, a surgeon much interested in drugs, are detailed by Dr. Alexander Brunschwig of Chicago, who, however, does not confide to the reader whether or no this is a pious tribute to an ancestor. Brunschwig in 1500 described at considerable length how the physicians deserted their patients while the surgeons remained at their own great risk to minister to the victims of the plague in 1473. He was also the author of two works on pharmacology, designed for the instruction of laymen. The origins and significance of the public health movement in the United States are set out with copious notes by Dr. Richard H. Schryock of Washington, and in his twenty-third study of palaeopathology Dr. Roy L. Moodie describes the surgery of pre-Columbian Peru. The cover bears a portrait of Ninian Pinkney (1811–77), a surgeon in the United States Navy, which illustrates the first portion of Captain Pleadwell's dutiful memoir of a predecessor. There are several editorials about societies interested in medical history, and other subjects; the first deals with the fifth annual meeting of the American Association of the History of Medicine, by the secretary, Dr. E. B. Krumbhaar; the third is an abstract of Professor W. H. Welch's address at the Institute of Medical History, which "has been seen but not corrected by" the speaker; and the fifth and last, an interesting account of the "Bibliotheca Osleriana" by the editor. The book reviews, always an attractive feature, are mainly by the editor, Dr. F. R. PACKARD, who must be heartily congratulated on the success of this new series of the *Annals*.

The January number contains eleven articles besides reviews, and an editorial on the inauguration of the Department of History of Medicine of Johns Hopkins University, and the opening of the William H. Welch Medical Library on October 17th last. At this ceremony Professor Karl Sudhoff gave an address, and the editorial appre-

[4] *Annals of Medical History.* New Series, Vol. I, No. 6, November, 1929; and New Series, Vol. II, No. 1, January, 1930. Edited by Frances R. Packard, M.D. New York: Paul B. Hoeber, Inc.; London: Baillière, Tindall and Cox. (Imp. 8vo, November, pp. 615-745, illustrated; January, pp. 134; illustrated. Subscription in Great Britain £2 5s. per volume of six numbers.)

priately contains the sketches of his and Professor Welch's life activities. While in North America Professor Sudhoff also gave addresses at New York, Boston, and Philadelphia, and the first of these, delivered at the Rockefeller Institute for Medical Research, and dealing with three problems of Hippocratic times, including the birthplace of the Father of Medicine, is printed in this number. In a generously illustrated article Dr. Burton Chance of Philadelphia writes on the aphorisms of Hippocrates, and in connexion with the discovery of a previously unknown drawing, Dr. Le Roy Crummer discusses the title-page of Vesalius's *Fabrica*. The career of M. J. B. Orfila (1787–1853) is described by Dr. B. Barker Benson, and the cover carries a portrait of this toxicological pioneer. The frontispiece represents the Reverend Stephen Hales, "the discoverer of blood pressure," and thus rightly illustrates Dr. R. H. Major's historical account of this subject. The state of general and medical science a hundred years ago is set out by Mr. Ivan C. Hall, who quotes freely from Guy's *Pocket Cyclopaedia* of 1829. In a carefully documented article, such as Captain F. L. Pleadwell always supplies, the history of Ninian Pinkney is continued from the previous number of the *Annals*. Sir Humphry Rolleston writes most attractively on Sir Thomas Browne, Dr. E. R. Wiese on Semmelweis, and Dr. E. P. Scarlet contributes a very interesting article on the psychological problems raised by Jean Paul Marat, who is said to have received "an honorary degree of M.D. at St. Andrews" in 1775. The labours and travels of Lazzaro Spallanzani, who, according to the naturalist Charles Bernet, discovered more truths in five years than entire academies have in half a century, are described by Professor Giuseppe Franchini of Bologna.

PHYSICAL SIGNS OF SURGICAL DISEASE.

MR. HAMILTON BAILEY'S *Demonstration of Physical Signs in Clinical Surgery*,[1] which was reviewed in these columns on January 28th, 1922, now appears in an enlarged and revised edition. Once it is granted that there is room for a textbook in which the physical signs of surgical diseases are brought together in a form suitable for easy reference, it can be said that the author has done a useful piece of work very well indeed. His survey is comprehensive, his style lucid, and his choice of illustrations, on the whole, excellent. The test of good illustrations is not merely that they are clearly reproduced; they must serve to emphasize or clarify points in the text. All the illustrations in this book pass the former test, but a few fail to pass the latter. For example, we are moved to ask what useful information is given by a photograph of a finger poised ready to percuss a shin, or of two test tubes held near a leg, or of a stethoscope in contact with the groin? A study of the index reveals the extraordinary extent of eponymic nomenclature; of the tests included no fewer than forty-six are named after their discoverers. The danger of such a nomenclature lies in the fact that often the individual is remembered but the test forgotten or misrepresented. For example, Nélaton, describing the well-known test associated with his name, wrote that if the patient lies upon the side *with the hip flexed to 90 degrees and slightly adducted* the line passing from the anterior superior spine to the most prominent part of the tuber ischii crosses the tip of the trochanter and the centre of the acetabulum. The line was thus used to distinguish between the second and third stages of hip disease. The fact that this simple test has been incorrectly recorded times out of number suggests the need for adopting an anatomico-pathological nomenclature, not necessarily replacing a nomenclature which is purely commemorative, but to be used in connexion with it. These, perhaps, are matters with which the third year student is not deeply concerned, and for him and for the student preparing for clinical examinations in surgery Mr. Hamilton Bailey's book may be recommended as a valuable collection of practically all the recognized signs used in clinical surgery.

NOTES ON BOOKS.

THE second edition of *Common Infections of the Female Urethra and Cervix*,[2] by Mr. FRANK KIDD and Mr. A. M. SIMPSON, shows little alteration from the first edition. As the authors explain, the methods of treatment described in the first edition have stood the test of time. A new chapter has, however, been added, descriptive of a more intensive treatment, which is calculated to hasten a cure, and of several minor improvements in regard to the technique of examination and treatment. This is a very useful little volume for those who are engaged either in the treatment of venereal disease or in gynaecological work. It is written in the most practical spirit and cannot fail to be helpful.

The issue of a second edition of KARSNER'S *Human Pathology*[3] within the short period of two years and a half points to a favourable reception of the book on the part of students and practitioners. In the new edition recent contributions to pathology, in so far as they bear upon the topics within the scope of the book, such as those relating to haemoglobin metabolism, pernicious anaemia, liver function and bile formation, have been included in the revision, but no alteration has been made in the general plan of the work. Recognizing the fundamental importance of pathological anatomy, the author has made that subject the basis of his classification, as in ordinary textbooks on pathological anatomy. His main purpose, however, has been to take a broader view and present the morphological alterations incident to disease in the light of modern views as to their functional significance—to consider pathological anatomy in its relation to the broader functional aspects of disease. This has necessitated a critical discussion of the explanations of disease and the interpretations of its phenomena, often highly theoretical, which are held at the present time. It is in subject-matter of this kind, where judgement and experience are called for in an especial degree, that the student feels the need of guidance and seeks a reliable authority. In this, the distinguishing feature of his work, the author must be considered to have been successful.

Aids to Forensic Medicine and Toxicology,[4] of which the ninth edition was noticed in these columns seven or eight years ago, has now been revised again by Dr. W. G. AITCHISON ROBERTSON of Edinburgh. The object of this little work remains as before—to help medical students in brushing up their knowledge before examination.

The Soya Bean and the New Soya Flour,[5] which has been translated from the Dutch, extols a food still strange to the West though long familiar to the East, particularly to China. In ancient times, it is claimed, this bean was one of the five important seeds ritually sown by the emperor. It is said to contain much fat and protein, to be satisfactory in its supply of vitamins, rich in phosphates, and almost starchless. As a plant the soya bean appears to be exceedingly adaptable, assimilative, drought-resistant, and economical in all its ways. Its cultivation is evidently being rapidly extended in the British colonies and in America. Dr. Berczeller has prepared a new kind of flour from the bean, which is declared to preserve all its nutritive properties with a palatable effect. A list of books on the subject is appended to the essay.

The Rhythms of Life, and other Essays in Science,[6] by Professor FRASER-HARRIS, recalls to mind the author's previous volumes on *Colour Thinking* and *The Sixth Sense*. It contains eighteen essays, many of which have already appeared in various journals; these are short, readable, and written in simple untechnical language, suited to the general reader. They hardly demand serious study, but, being full of information, their perusal in spare moments will impart to the reader many things worth knowing. The following are among the subjects dealt with: Animal electricity and heat, circulations, the eye as camera, prediction in biology, the litany, the sensitiveness of women, ventilation, vital force, the nervous system, the microscope, taste, colour, suspended animation, and lost arts.

diagnosis of parasitic worms and their eggs are discussed in great detail. A very useful chapter dealing with scientific nomenclature is added. The book comprises 616 pages and contains 297 illustrations. With the exception of a few photomicrographs the figures are excellent.

In the trematoda the commonly accepted scheme of classification, based as it is largely on the morphology of the adult, is considerably modified, great stress being laid on the importance of the excretory system of the cercariae and adult, and especially of the first-named. Formulas relating to this system in the miracidia and cercariae are included in the definition of some of the suborders and superfamilies, but the characters of the genera dealt with are not defined. Adult worms are referred to as maritae, metacercariae as adolescariae, and the sporocysts and rediae as parthenetic generations. These terms will be new to English students, but they are defined. As the author rightly points out, "the excretory system can be studied satisfactorily only in the living material, and then only in species sufficiently transparent to permit the investigator to observe the various parts of the system in a fluke compressed under a microscope cover-glass." It will therefore be clear that the value of the excretory cells from the classification point of view is very limited, and especially is such the case with medical and veterinary students, who are, for the most part, concerned primarily with the accurate diagnosis of helminthic infections in man and animals. It remains to be seen whether the classification based on the nature of the excretory system is more constant and reliable than that accepted up to the present by other helminthologists. The general description of the trematode worms is admirable, and especially so in the case of the schistosomes. The account of the cestoda is very well done, and contains all that the student requires for the diagnosis of tapeworm infections. Helminthologists will, however, probably not agree with the author's limitation of the genus Dibothriocephalus to species which, in the adult stage, occur in fish, or to the similar restriction of species of the genus Diphyllobothrium, to those adults of which only the larval stages occur in fish. The descriptions of the nematode parasites are very full, clear, and up to date, the hookworms and filariidae being especially well done. At the end of the volume there is a very long and elaborate diagnostic key for the "identification adult worms and larvae in advanced stages of development." Keys are often very useful, but here the field is so vast and the species so varied that diagnostic characters cannot be satisfactorily embodied in a key.

The author has a wide and a practical knowledge of the subject, and has had considerable experience in teaching. From a student's point of view, however, it is perhaps a little unfortunate that a greater distinction is not made between the commoner and the rarer parasites. Dr. Faust rightly points out that he "has depended on the work of his colleagues for much of the evidence and many of the views expressed"; the same remark applies equally well to many of the illustrations reproduced. Generally speaking, the book is excellent, and can be recommended with confidence to all who wish to take up the study of human helminthology, and to teachers who desire to have a handy book for ready reference.

CLINICAL ATLAS OF BLOOD DISEASES.

In their vade-mecum for haematologists[3] Drs. A. PINEY and S. WYARD have compressed into less than a hundred pages most of the information needed for the rough diagnosis of blood diseases from blood films; though, of course, haematologists cannot live by dried films alone. The book is intended chiefly for the use of the practitioner, and it may be helpful to those who have time to attend to the clinical pathology of their cases, and who are already familiar with haematological technique; possibly also it may be useful in clinical laboratories. Besides the very concise, perhaps too concise, account of a number of clinical states, some of which cannot really be regarded as blood diseases, the feature of this book is the coloured plates which represent with fair accuracy the appearances of the stained cells met with in the blood of these diseases. The films from which the pictures have been prepared are stated to be all stained by Jenner-Giemsa method; they are, however, not uniformly stained (compare the pictures of polymorphonuclear leucocytes in plates 21, 22, and 24). Plates 14 and 19, showing reticulocytes, are certainly drawn from films which had been stained by some other process. This is unfortunate, and may easily betray into serious error the practitioner who relies on blood films for diagnosis. The eosinophil cell in plate 5 is noted as being stained by Jenner (p. 8), but the picture is not very accurate; the nuclei of Jenner-stained eosinophil cells stain pure methylene blue and have no red or violet tint, and the granules are pinker and coarser. Readers will be grateful for the admirable glossary of haematological terms which so often make a stumbling-block for the inexperienced worker. A regular index would, we think, be more useful than a table of contents. The text is remarkably free from misprints, but we note on page 68 "myeblasts" for myeloblasts. The publishers are to be congratulated upon the production of so comprehensive a book at the moderate price of 12s. 6d.

[3] *Clinical Atlas of Blood Diseases.* By A. Piney, M.D., M.R.C.P., and Stanley Wyard, M.D., M.R.C.P. Churchill's Empire Series. London: J. and A. Churchill. 1930. (5¼ × 8¼, pp. xv + 98; 36 plates. 12s. 6d. net.)

"ANNALS OF MEDICAL HISTORY."[4]

THE concluding instalment of the first volume of the new series of the *Annals of Medical History*, now a bimonthly instead of a quarterly publication, opens with the first William Snow Miller Lecture, given by Professor T. Wingate Todd of Cleveland, in March, 1928, at the University of Wisconsin on "The medieval physician," which pleasantly touches on Salerno and Padua, and on Paracelsus and other men of old time. Dr. Harry Friedenwald contributes a learned and beautifully illustrated account of the manuscript medical works of Isaac Judaeus in the ninth century, and on the diploma of Copilius Pictor or Koppel Mehler, a Jewish graduate of Padua in 1695. The activities of Hieronymus Brunschwig (1450–1533) of Strasbourg, a surgeon much interested in drugs, are detailed by Dr. Alexander Brunschwig of Chicago, who, however, does not confide to the reader whether or no this is a pious tribute to an ancestor. Brunschwig in 1500 described at considerable length how the physicians deserted their patients while the surgeons remained at their own great risk to minister to the victims of the plague in 1473. He was also the author of two works on pharmacology, designed for the instruction of laymen. The origins and significance of the public health movement in the United States are set out with copious notes by Dr. Richard H. Schryock of Washington, and in his twenty-third study of palaeopathology Dr. Roy L. Moodie describes the surgery of pre-Columbian Peru. The cover bears a portrait of Ninian Pinkney (1811–77), a surgeon in the United States Navy, which illustrates the first portion of Captain Pleadwell's dutiful memoir of a predecessor. There are several editorials about societies interested in medical history, and other subjects; the first deals with the fifth annual meeting of the American Association of the History of Medicine, by the secretary, Dr. E. B. Krumbhaar; the third is an abstract of Professor W. H. Welch's address at the Institute of Medical History, which "has been seen but not corrected by" the speaker; and the fifth and last, an interesting account of the "Bibliotheca Osleriana" by the editor. The book reviews, always an attractive feature, are mainly by the editor, Dr. F. R. PACKARD, who must be heartily congratulated on the success of this new series of the *Annals*.

The January number contains eleven articles besides reviews, and an editorial on the inauguration of the Department of History of Medicine of Johns Hopkins University, and the opening of the William H. Welch Medical Library on October 17th last. At this ceremony Professor Karl Sudhoff gave an address, and the editorial appre-

[4] *Annals of Medical History.* New Series, Vol. I, No. 6, November, 1929; and New Series, Vol. II, No. 1, January, 1930. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber, Inc.; London: Baillière, Tindall and Cox. (Imp. 8vo, November, pp. 615-745, illustrated; January, pp. 134; illustrated. Subscription in Great Britain £2 5s. for volume of six numbers.)

priately contains the sketches of his and Professor Welch's life activities. While in North America Professor Sudhoff also gave addresses at New York, Boston, and Philadelphia, and the first of these, delivered at the Rockefeller Institute for Medical Research, and dealing with three problems of Hippocratic times, including the birthplace of the Father of Medicine, is printed in this number. In a generously illustrated article Dr. Burton Chance of Philadelphia writes on the aphorisms of Hippocrates, and in connexion with the discovery of a previously unknown drawing, Dr. Le Roy Crummer discusses the title-page of Vesalius's *Fabrica*. The career of M. J. B. Orfila (1787–1853) is described by Dr. B. Barker Beeson, and the cover carries a portrait of this toxicological pioneer. The frontispiece represents the Reverend Stephen Hales, "the discoverer of blood pressure," and thus rightly illustrates Dr. R. H. Major's historical account of this subject. The state of general and medical science a hundred years ago is set out by Mr. Ivan C. Hall, who quotes freely from Guy's *Pocket Cyclopaedia* of 1829. In a carefully documented article, such as Captain F. L. Pleadwell always supplies, the history of Ninian Pinkney is continued from the previous number of the *Annals*. Sir Humphry Rolleston writes most attractively on Sir Thomas Browne, Dr. E. R. Wiese on Semmelweis, and Dr. E. P. Scarlet contributes a very interesting article on the psychological problems raised by Jean Paul Marat, who is said to have received "an honorary degree of M.D. at St. Andrews" in 1775. The labours and travels of Lazzaro Spallanzani, who, according to the naturalist Charles Bernet, discovered more truths in five years than entire academies have in half a century, are described by Professor Giuseppe Franchini of Bologna.

PHYSICAL SIGNS OF SURGICAL DISEASE.

MR. HAMILTON BAILEY'S *Demonstration of Physical Signs in Clinical Surgery*,[1] which was reviewed in these columns on January 28th, 1928, now appears in an enlarged and revised edition. Once it is granted that there is room for a textbook in which the physical signs of surgical diseases are brought together in a form suitable for easy reference, it can be said that the author has done a useful piece of work very well indeed. His survey is comprehensive, his style lucid, and his choice of illustrations, on the whole, excellent. The test of good illustrations is not merely that they are clearly reproduced; they must serve to emphasize or clarify points in the text. All the illustrations in this book pass the former test, but a few fail to pass the latter. For example, we are moved to ask what useful information is given by a photograph of a finger poised ready to percuss a shin, or of two test tubes held near a leg, or of a stethoscope in contact with the groin? A study of the index reveals the extraordinary extent of eponymic nomenclature; of the tests included no fewer than forty-six are named after their discoverers. The danger of such a nomenclature lies in the fact that often the individual is remembered but the test forgotten or misrepresented. For example, Nélaton, describing the well-known test associated with his name, wrote that if the patient lies upon the side *with the hip flexed to 90 degrees and slightly adducted* the line passing from the anterior superior spine to the most prominent part of the tuber ischii crosses the tip of the trochanter and the centre of the acetabulum. The line was thus used to distinguish between the second and third stages of hip disease. The fact that this simple test has been incorrectly recorded times out of number suggests the need for adopting an anatomico-pathological nomenclature, not necessarily replacing a nomenclature which is purely commemorative, but to be used in connexion with it. These, perhaps, are matters with which the third year student is not deeply concerned, and for him and for the student preparing for clinical examinations in surgery Mr. Hamilton Bailey's book may be recommended as a valuable collection of practically all the recognized signs used in clinical surgery.

[1] *Demonstrations of Physical Signs in Clinical Surgery.* By Hamilton Bailey, F.R.C.S.Eng. Second edition, revised and enlarged. Bristol: J. Wright and Sons, Ltd. London: Simpkin Marshall, Ltd. 1930. (Med. 8vo, pp. xviii + 268; 306 figures. 21s. net.)

NOTES ON BOOKS.

THE second edition of *Common Infections of the Female Urethra and Cervix*,[6] by Mr. FRANK KIDD and Mr. A. M. SIMPSON, shows little alteration from the first edition. As the authors explain, the methods of treatment described in the first edition have stood the test of time. A new chapter has, however, been added, descriptive of a more intensive treatment, which is calculated to hasten a cure, and of several minor improvements in regard to the technique of examination and treatment. This is a very useful little volume for those who are engaged either in the treatment of venereal disease or in gynaecological work. It is written in the most practical spirit and cannot fail to be helpful.

The issue of a second edition of KARSNER'S *Human Pathology*[7] within the short period of two years and a half points to a favourable reception of the book on the part of students and practitioners. In the new edition recent contributions to pathology, in so far as they bear upon the topics within the scope of the book, such as those relating to haemoglobin metabolism, pernicious anaemia, liver function and bile formation, have been included in the revision, but no alteration has been made in the general plan of the work. Recognizing the fundamental importance of pathological anatomy, the author has made that subject the basis of his classification, as in ordinary textbooks on pathological anatomy. His main purpose, however, has been to take a broader view and present the morphological alterations incident to disease in the light of modern views as to their functional significance—to consider pathological anatomy in its relation to the broader functional aspects of disease. This has necessitated a critical discussion of the explanations of disease and the interpretations of its phenomena, often highly theoretical, which are held at the present time. It is in subject-matter of this kind, where judgement and experience are called for in an especial degree, that the student feels the need of guidance and seeks a reliable authority. In this, the distinguishing feature of his work, the author must be considered to have been successful.

Aids to Forensic Medicine and Toxicology,[8] of which the ninth edition was noticed in these columns seven or eight years ago, has now been revised again by Dr. W. G. AITCHISON ROBERTSON of Edinburgh. The object of this little work remains as before—to help medical students in brushing up their knowledge before examination.

The Soya Bean and the New Soya Flour,[9] which has been translated from the Dutch, extols a food still strange to the West though long familiar to the East, particularly to China. In ancient times, it is claimed, this bean was one of the five important seeds ritually sown by the emperor. It is said to contain much fat and protein, to be satisfactory in its supply of vitamins, rich in phosphates, and almost starchless. As a plant the soya bean appears to be exceedingly adaptable, assimilative, drought-resistant, and economical in all its ways. Its cultivation is evidently being rapidly extended in the British colonies and in America. Dr. Berczeller has prepared a new kind of flour from the bean, which is declared to preserve all its nutritive properties with a palatable effect. A list of books on the subject is appended to the essay.

The Rhythms of Life, and other Essays in Science,[10] by Professor FRASER-HARRIS, recalls to mind the author's previous volumes on *Colour Thinking* and *The Sixth Sense*. It contains eighteen essays, many of which have already appeared in various journals; these are short, readable, and written in simple untechnical language, suited to the general reader. They hardly demand serious study, but, being full of information, their perusal in spare moments will impart to the reader many things worth knowing. The following are among the subjects dealt with: Animal electricity and heat, circulations, the eye as camera, prediction in biology, the litany, the sensitiveness of women, ventilation, vital force, the nervous system, the microscope, taste, colour, suspended animation, and lost arts.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT, 1928-29.

(*Continued from page 560.*)

II.

EXPERIMENTAL MEDICINE.

SIR THOMAS LEWIS continues to direct the Council's Department of Clinical Research and the Cardiographic Department of University College Hospital Medical School. In particular during the past year observations have been continued upon the peripheral circulation, and an unusual case of the Donath-Landsteiner type, in which the red blood cells exposed to cold *in vitro* became haemolysed on rewarming, has been specially studied. Dr. R. Grant and Dr. D. Jones have just concluded a difficult investigation into the vascular response to injury with especial reference to the chemical aspects of the reaction of the skin. At St. Thomas's Hospital Professor Hugh MacLean and his colleagues have continued their inquiries into the physiology of digestion; and the automatic regulation of gastric acidity is the subject of experiments now in progress. On the surgical side an investigation is proceeding under Mr. B. W. Williams on the treatment of anaerobic infections and the toxaemias of acute intestinal obstruction by means of anti-*welchii* serum. At the London Hospital various aspects of epilepsy have been studied by members of the unit. Dr. Russell Brain has been investigating the causation of the convulsive states, and with other workers he has shown that epileptics vary considerably in their responses to sleep and wakening, and that abnormalities occur in the level of the cholesterol in the blood plasma. Dr. H. D. Kay continues his work upon phosphatase in bones and tissues in various diseases. At St. Bartholomew's Hospital Dr. G. C. Linder and Dr. C. F. Harris have investigated the influence of parathyroid extract, thyroid extract, and calcium salts in cases of tetany after operations on the thyroid gland. Dr. R. Hilton has studied the effects of deep *x*-ray therapy on the lungs, and with Professor F. R. Fraser has made observations of the circulation in heart failure by measuring oxygen utilization in the cerebral circulation in man. At Guy's Hospital Dr. A. C. Hampson and Dr. E. C. Warner have been studying various aspects of pernicious anaemia under the direction of Dr. E. P. Poulton. The work of Professor E. Mellanby and his assistants at Sheffield has mostly been concerned with the relation of diet to infection. It was found that when rats were fed on a diet deficient in vitamin A they nearly always died of septic infection. The effect of vitamin A preparations in a few cases of puerperal septicaemia has been investigated, and it has been shown that a definite increase in resistance is given by intensive vitamin A therapy. (See *British Medical Journal*, October 20th, 1928, p. 691, and June 1st, 1929, p. 984.) The subject of ergotism has been studied at the Field Laboratories, and it has been found possible to prevent the appearance of the usual symptoms and signs by giving certain protective foodstuffs. In the course of the experiments it was observed that ergot has powerful calcifying properties owing to the presence of vitamin D. Mr. Lambert Rogers in Cardiff has been studying periarterial sympathectomy, while in Edinburgh various workers have been studying such subjects as the effects of excessive administration of irradiated ergosterol (Dr. C. P. Stewart) and the response of the heart to digitalis and strophanthin (Dr. A. R. Gilchrist). In the department of surgery experiments are in progress for the study of the pulmonary circulation at all ages in health by means of the "collodion corrosion" method. Dr. A. Rowand, at St. Andrews, is working at the James Mackenzie Institute, and aims at obtaining a complete study of the health of 500 children from birth to school age.

CHILD LIFE.

Work on the causes of neo-natal death, by Dr. J. X. Cruickshank at Glasgow, and on foetal development, by Miss E. Hewer in London, continues; while in Professor Winifred Cullis's department Miss M. Bond and Miss S. Widdows have been working on the composition of milk secreted after the first month of lactation. Work on the metabolism of children at Glasgow has consisted chiefly in studies, by Dr. S. Graham and Dr. N. Morris, on the acid-base equilibrium in various conditions. In Birmingham Dr. Leonard Parsons and other workers have investigated further the biochemistry of coeliac disease and also the effects of variation in the diet of a group of children in the convalescent stage of acute rheumatism. At University College, London, Dr. H. A. Harris continues his studies in growth, and he has shown that cod-liver oil, by virtue of the presence of both vitamins A and D, possesses advantages over irradiated ergosterol in the treatment of rickets. Work has also been carried out on anaemia in infancy by Dr. Helen Mackay and on rheumatism by Dr. Carey F. Coombs at Bristol, and by Dr. R. C. Lightwood in Kensington.

HUMAN NUTRITION.

The work on national dietaries being carried on at Glasgow by Professor E. P. Cathcart has been making progress, and the analysis over a suitable period of the diets in a series of typical households in various towns is proceeding. Dr. J. B. Orr of Aberdeen, with helpers, has continued his work on the relationship of iodine in foodstuffs to the distribution of goitre. The Council has again received a grant from the Empire Marketing Board for investigation into the vitamin content of various Empire food substances. Dr. S. S. Zilva, with assistants, is doing this work at the Lister Institute, and in his studies on the antiscorbutic factor in lemon juice he has found and is investigating the properties of a third and "thermolabile" factor. With Miss M. Soames and Miss E. O. V. Perry he has begun an inquiry into the accuracy of some methods of assay of the vitamins, and the object is to see whether shorter and cheaper methods can be found without loss of accuracy. Professor J. C. Drummond's work on the comparison of the biological method of assay of vitamin A with the colorimetric and spectrographic methods has been completed at University College. Work on vitamin B_1 by Dr. Guha and on vitamin B_2 by Dr. B. T. Narayanan has also been carried out, and it has been shown that "bios" is not identical with any one of the known vitamins of the B group. At Cambridge Dr. L. J. Harris and Dr. T. Moore have studied the effects of giving massive doses of irradiated ergosterol. Evidence has been obtained that the ill effects are due to overdosage with vitamin D itself and not to impurities produced during irradiation. Co-operating with this work Mr. Innes has found that the microscopic changes are the opposite of those found in rickets. At King's College for Women Professor V. H. Mottram, with Miss G. A. Hartwell and Miss W. A. Clifford, has been making trials of the relative values of brown bread and white bread in the diet of rats.

DENTAL DISEASE.

The Dental Board of the United Kingdom makes an important grant towards work in this subject. Dr. E. W. Fish has continued his work on the changes in dentine caused by injury, erosion, or caries. Mrs. M. Mellanby has been working on the relation between the original structure of the periodontal tissues and their liability to infection, and also on the relation between diet and liability to infection under normal and abnormal conditions of structure. She is still supervising the inquiry proceeding at Birmingham into the influence of diet on the development and extension of caries in the teeth of children.

CARDIO-VASCULAR, EXCRETORY, AND NERVOUS SYSTEMS.

In addition to the [illegible] University College, London, Dr. J. C. [illegible] with Dr. F. Ellis, has studied special aspects of the circulatory system.

These two workers made studies of certain of the athletes at the Olympic Games at Amsterdam in 1928, and, with Miss N. Regan, Dr. Bramwell is investigating the cardiac *complications of pregnancy and labour*. At Cambridge Dr. G. Anrep's work on heart muscle has shown that the coronary flow is determined by two factors: the tone of the coronary blood vessels and the duration and relative strength of the cardiac contraction. Professor J. Shaw Dunn has done further work at Manchester on the experimental production of nephritis, and Dr. J. Gray of Aberdeen has continued his study of nephritis by microscopic and experimental methods, and his results tend to confirm Fishberg's contention that primary high blood pressure produces renal arterio-sclerosis. Miss L. M. Pickford, with Professor Verney, is investigating the effect on one part of the kidney of circulatory arrest in the other. Work at Edinburgh by Sir E. Sharpey-Schafer and others has been carried out on nerve regeneration, and a grant made to Sir Charles Sherrington at Oxford was used for special apparatus for the study of mechanical and electrical responses in mammalian reflexes. At the National Hospital for Nervous Diseases, Queen Square, London, Dr. Denny-Brown is making various investigations in clinical neurology, and at the same hospital Dr. E. A. Blake Pritchard is working at the varieties of knee-jerk met with in nervous diseases. Dr. R. S. Allison of Ruthin Castle, Wales, is inquiring into the incidence and distribution of disseminated sclerosis in North Wales with a view to finding predisposing causes in the environment or habits of the persons affected. Work on mental disorders is being conducted at Birmingham, where Dr. F. A. Pickworth is studying the basal metabolism in insane subjects; and at the Maudsley Hospital Dr. F. L. Golla and Miss S. Antonoritch have been studying variations in certain physiological values in normal and abnormal mental states. The tone of the skeletal muscle during intellectual exercise has also been investigated.

Internal Secretions.

Professor V. Korenchevsky, assisted by Mrs. M. Dennison, has continued his studies on the pituitary gland and on the testis. He has shown that the sexual hormones are not confined in the latter organ to the interstitial cells, but are present also in the generative testicular cells. At University College Dr. A. S. Parkes and Mr. G. F. Marrian continue their work on the female sexual glands. Dr. Parkes has found that the presence of the anterior lobe of the pituitary gland is essential for ovulation, and Mr. Marrian, by administering anterior pituitary substance, has been able to restore ovarian activity lost during vitamin B deficiency. Work on the suprarenal glands has been conducted by Dr. E. Noble Chamberlain at Liverpool and Dr. G. P. Crowden at University College, London, and the latter worker has shown that external cold, if it persists for some time, produces exhaustion of the adrenaline store of the suprarenal glands. Dr. G. Scott Williamson's work with Dr. I. H. Pearse on the thyroid gland has led him to believe that there is a close functional and morphological relationship between the thyroid, the thymus, and the lymphatic system, such as has not before been suggested. Work on insulin and diabetes has been continued by Dr. R. D. Lawrence at King's College Hospital, and at Sheffield Dr. G. A. Clark has been investigating the hyperglycaemia produced by the injection of pituitrin.

Tuberculosis, Streptococcal Infections, and Venereal Disease.

Dr. A. Stanley Griffith's experiments with B.C.G. vaccine have shown that a high degree of resistance to tuberculosis can be conferred upon a calf by either inoculation or oral administration of B.C.G. Professor S. L. Cummins at Cardiff has continued his work on laboratory methods for gauging the progress of cases of tuberculosis. With Dr. W. H. Tytler, Mr. E. T. Waters has been attempting to find constituents of the tubercle bacillus which can be recognized by specific reactions in the urine of tuberculous patients with the object of providing a direct test for the presence of active disease. Dr. Tytler's work on the constitution of tuberculin is also regarded as having an important bearing on standardization. Special investigations *are being made into the incidence of bovine tuberculosis* in a special area in Ayrshire, where a group of herds will be examined. Work on the streptococci is proceeding in several quarters. Dr. Leonard Colebrook, with Mr. Burt-White, has investigated puerperal pyrexia, with the unexpected but important result that of all the recognized febrile disturbances of the puerperium only a small percentage is associated with infection by *Streptococcus pyogenes*. Other workers have studied the mechanism of natural recovery from puerperal infection and the causes of puerperal morbidity. Work on venereal diseases supported by the Council is continued at St. Thomas's Hospital by Colonel L. W. Harrison and Dr. T. E. Osmond.

Virus Diseases—Distemper.

The special research proceeding at Hampstead on virus diseases has already been mentioned. The details of the work on canine distemper are elaborated in this section. The method devised for the protective immunization of dogs is now in use on a large scale, and after two inoculations a lasting and solid immunity is obtained. Over 2,000 doses of this distemper vaccine and virus have been distributed, and since last spring the prophylactic has been issued commercially to veterinary practitioners by Messrs. Burroughs Wellcome and Co. Severe reactions, which have occurred in less than 1 per cent. of the many thousands of dogs treated, seem to be due to the condition of certain animals at the time of inoculation. It is therefore strongly stressed that the animals should be in perfect health before immunization is attempted. Work is now proceeding in an effort to obtain an immune serum: Dr. P. P. Laidlaw and Mr. G. W. Dunkin are investigating this problem.

Chemotherapy: Tissue Culture: Cancer.

The chemical members of the Chemotherapy Committee are appointed by the Department of Scientific and Industrial Research, which makes grants for the expenses of the purely chemical part of the work. New chemical compounds of possible therapeutic value have been tested in various centres, and most of them have been found to be inactive. There are, however, some important exceptions: several compounds supplied by Professor R. Robinson have been found to be highly active against bird malaria, while Professor C. Browning has found that some of Professor J. B. Cohen's substances are active trypanocidal agents of a new type. The Council has continued to contribute largely to the maintenance of the Strangeways Laboratory at Cambridge, and has recently provided the laboratory with a new building for the housing of *x*-ray apparatus. Mr. C. H. Waddington has begun to investigate methods of growing the early stages of entire chick embryos *in vitro*, and it has already been possible to obtain from embryos which have been incubated from three to twenty-four hours before explantation nearly normal differentiation of the growing tissues *in vitro* for three to four days. Working on the effects of radiation upon tissue cultures, Miss S. E. Cox has found that, for a given dose of *x* rays, retardation of cell growth was greater with irradiation of greater intensity over a short period of time than when the same dose was given for a longer time with smaller intensity. Work on problems of malignant disease carried on at the National Institute has already been mentioned. In addition to this, Dr. Helen Chambers has continued her experiments at Middlesex Hospital to test the immunity to tumours given by tissue extracts of tumour-bearing and normal animals. It has seemed from preliminary work that there is a reduction in the number of tumours after treatment with tissue extracts of tumour-bearing animals. Mr. W. B. Gabriel, at St. Mark's Hospital, London, has now obtained a systematic record of all cases of cancer of the rectum admitted to the hospital from 1910 to the present time, and this record well illustrates the importance of taking a minimum of five years as a basis for any estimations of cure after radical operation.

RADIUM AND LIGHT THERAPY.

The stock of radium held by the Council on behalf of H.M. Government is supplemented by a further quantity provided by the British Empire Cancer Campaign, and the bulk of this total stock is now employed in a scheme of co-ordinated research into the radium treatment of cancer. The annual report on this work is published separately. Dr. H. A. Colwell at King's College Hospital has, with Dr. E. F. Creed, completed an investigation of the action of primary and secondary α rays, and the β and γ radiations of radium upon red blood corpuscles and haemolysis, complement and agglutinins. Researches into the biological actions of light have included statistical inquiries in populations of mice into the effects of irradiation upon the resistance of the body to a bacterial infection. With Professors Topley and Greenwood, Professor Leonard Hill has been co-operating in such an experiment for several months, and the results will be published as soon as they are available.

VISION AND HEARING.

Work in each of these subjects deals both with the purely physiological aspect and with the special problems of industry and the services. At University College, London, Dr. and Mrs. W. S. Duke-Elder have continued their work on intraocular pressure and the pathology of glaucoma. A detailed chemical and physical study of the vitreous body has been completed. At the request of the Admiralty, all the visual standards now in force in the navy are being reviewed by the Committee on the Physiology of Vision, and a full report, embodying recommendations for the amendment of the existing standards, is in course of preparation. On the industrial side, Mr. H. C. Weston and Mr. S. Adams have made further experiments in the use of special spectacles in very fine processes, and the results recently published show that persons with perfectly normal vision as well as those with visual defects derive much benefit from the use of these spectacles. Problems of localization by hearing have been investigated in different centres; under Mr. F. C. Bartlett at Cambridge, Miss [illegible] investigated [illegible] in binaural [illegible] E. M. Massey has investigated disturbances of auditory after-[illegible] Hilton-Brown localization produced by one-sided and binaural stimulation.

GENERAL PHYSIOLOGY, PATHOLOGY, AND BIOCHEMISTRY.

Work under Professor A. V. Hill at University College, London, has been assisted by grants to several workers. Mr. H. V. Horton's researches tend to confirm the theory that the reversible loss of excitability by an isolated frog's muscle is due to an escape of potassium from the fibres into the interspaces. Mr. and Mrs. Eggleton have studied the diffusion of lactic acid through living muscles, and have also continued their studies of creatine and of the phosphorus compounds concerned in muscular contraction. A grant has been made to Professor J. J. R. Macleod of Aberdeen for work on the formation of glycogen in the muscles of warm-blooded animals and its relation to lactic acid formation. In pathology particular interest is centred round the work on lymphadenoma conducted by a large team at St. Bartholomew's Hospital under the Rose bequest. Experimental studies directed by Dr. M. H. Gordon have consisted in attempts to reproduce the disease with material derived from proved cases. Special endeavour is being made to show whether Hodgkin's disease is or is not an infection by organisms of the family of fungi. An account of the work of Professor W. Bulloch of the London Hospital with Dr. L. H. Lampitt and Mr. T. H. Bushill of the Research Laboratories of Messrs. J. Lyons and Co., upon the preparation of catgut for surgical use, has already been published separately (*British Medical Journal*, November [illegible], 1929, p. 918). The work on enteric carriers by Professors R. Muir and C. Browning at Glasgow has been concluded and the results will soon be published. With Professor H. R. Dean at Cambridge, Dr. R. A. Webb has studied the effects of varying concentrations of sodium chloride upon the serum precipitation reaction, and the use of antitoxin as antigen in this reaction. Dr. L. E. H. Whitby, at the Middlesex Hospital, has been investigating the frequency of *B. welchii* infections of the biliary tract. Under biochemical studies may be mentioned investigations by Dr. C. J. Imrie at Sheffield into the metabolism of creatine, and work by Dr. F. Dickens with Professor C. E. Dodds at Middlesex Hospital, London, which has given a satisfactory method for standardizing the water-soluble oestrus-hormone.

ANAESTHETICS.

At Manchester Professor H. B. Dixon, with Dr. W. E. Higgins, has examined many cylinders of nitrous oxide, and in all the samples tested carbon monoxide was present in amounts varying from 5 to 40 parts per million. Tests of the nitrate used in the manufacture showed that it was of high purity, but that small fragments of wood from the barrels in which it was supplied became mixed with the charge and so adulterated the product.

STATISTICS.

Much of the work under this heading has again consisted in giving statistical help to research workers in other departments. The analysis of the anthropometric data collected for a committee of the Board of Education has been carried to a point that will permit a final report. A special research committee has been appointed by the Council, under the chairmanship of Sir George Newman, to make a thorough study of the outbreaks of minor epidemic illnesses in schools, and the statistical part will be undertaken by the Statistical Committee's staff. Dr. Matthew Young has been collecting data at a large general hospital with the object of finding whether the incidence of some well-defined diseases is higher among people of a particular physical type or bodily conformation than among the general population.

INDUSTRIAL HEALTH.

The Industrial Health Research Board has changed "health" for "fatigue" in its name, for, [illegible] concern the beginning essentially with the special problems long hours of work during the war, the Board now attention mostly directed towards problems other those of fatigue as such. Dr. A. B. Hill's [illegible] incidence of sickness among printers has been concluded, [illegible] and it is shown that printers have a low incidence of sickness except during the first age period of working life (*British Medical Journal*, March 30th, 1929, p. 611). Work on industrial psychology has proceeded at various centres. At Manchester, under Professor T. H. Pear, Mrs. E. M. Henshaw and Miss P. G. Holman have investigated the extent to which the effects of training are transferable from one skilled manual operation to another. Studies of problems in manual repetition work have been continued by several workers, and the results, now published, suggest that complete uniformity of task is less productive than a degree of variety. Mr. H. C. Weston has been testing the value for the health of factory workers of using special window glass which is transparent to ultra-violet rays.

CONCLUSION.

The concluding sections of the report deal with the work of the travelling Fellows appointed by arrangement with the Rockefeller Foundation and with the Dorothy Temple Cross Research Fellowships in Tuberculosis. Reference is also made to the financial support received by the Council from various sources and to certain gifts, including that of a valuable collection of chemical preparations [illegible] by the late Professor J. L. W. Thudichum, "the first research worker to be appointed under the Privy Council

---

THE Church of England Zenana Missionary Society, which is celebrating its jubilee during 1930, has issued an appeal for a thank-offering fund of £100,000, to be completed by March 31st. One donation of £20 has been offered conditionally on ninety-nine similar gifts being obtained by the end of this month. The society sent out the first European woman doctor to India—Dr. Fanny Butler—and the work started has now expanded into the conducting of two fully equipped hospitals and twenty-seven dispensaries, as well as a considerable amount of itinerant medical work. Contributions should be sent to the financial secretary of the Society, 19–21, Southampton Street, Fitzroy Square, W.1.

British Medical Journal.

SATURDAY, MARCH 29TH, 1930.

INJURIES OF THE KNEE-JOINT.

THE gross anatomy of the human body is so familiar to all of us that we seldom pause among our daily preoccupations to ponder for a moment on the variety of the mechanical devices through which movement between its various segments is made possible, regulated, and limited. The nature and range of the principal movements of the knee-joint and of the elbow-joint are not very different, but how different the articulating surfaces concerned and the mechanism of regulation! The knee is the largest joint in the body, and although it has to withstand tremendous stresses and shocks, yet it admits of a greater range of flexion and extension than any other joint. So extensive is this movement that at the extreme limit of flexion of the normal joint the chief articular surfaces of the long bones concerned may be said to be almost entirely dislocated from one another.

These things being so, we are quite prepared to accept without question the opening sentence of Mr. H. A. T. Fairbank's paper, which is published in this issue (p. 581), and are not surprised to read that the knee-joint is more often injured than any other [illegible] the human body. In pre-Listerian days, when [illegible] int was sacrosanct as far as surgery was [illegible] the student used to be told of the im- [illegible] the semilunar cartilages, which were sup- [illegible]d by their adaptability and relations to make up for the prima facie mechanical weakness of the joint; but nowadays, like the adult spleen, the vermiform appendix, and the gall-bladder, they rank as superfluities, unearned increments, with which man has been endowed by his ancestors, and Mr. Fairbank has removed three out of the four cartilages of one patient, while it is well known that many men now play football *minus* one or more of the interarticular menisci. The explanation of this discrepancy between theory and practice may, we think, be found to lie in the neglect of some anatomists of past generations to take into account the very important part played by the muscles which control a joint and which through their postural tone exert such a great influence on its efficiency. In no joint is this action more in evidence than in the knee, where muscular atrophy is so often a source of disability, persisting after the original synovitis or other lesion of the joint is healed. Mr. Fairbank does well to insist upon the importance of trying to prevent or at least to cure this muscular wasting by the early persistent and discriminating use of faradism to all the muscles concerned, including the tensor fasciae femoris, until it is permissible to employ that best physiological means of muscle development—namely, volitional contraction. For the thoughtful student of the subject will not forget that muscular atrophy after joint injury is not a *mere* muscular phenomenon, but the outward sign of a neuro-muscular cycle.

Hilton's advocacy of physiological rest, when not intelligently followed, has done a good deal of harm. In nine cases out of ten a sprained ankle or knee is the better for use when properly strapped or bandaged. The chief contraindication for such use is pain thereby evoked, on which subject the patient is entitled to express an opinion. Walking, cycling, and rowing are permissible at a much earlier stage than golf and other ball games which involve exposure of the joint to sudden strains and twists. When from a faulty early treatment or other circumstances synovitis has become chronic and adhesions have formed Mr. Fairbank, with other surgeons, advises examination under deep anaesthesia and the breaking down of any adhesions which may be found to prevent not only flexion and extension, but full normal rotation. Let the surgeon remember that bruising of articular cartilage may be the cause of pain after use which only disappears after weeks or months. All surgeons with much experience of injuries of joints probably have a pretty clear idea of the clinical syndrome which leads them to make a diagnosis of "strain of ligament." Yet it may be questioned whether such a diagnosis rests on any very firm objective basis. It is not easy to form an exact mental picture of the damage done by strain to such an inelastic structure. A ligament may be ruptured, though it more often happens that it is torn away from one or more of its bony attachments, or else the bone itself gives way and a small scale of it is carried away attached to the ligament which is inserted into it. In this connexion it is well to bear in mind that ligaments *in vivo* are not the isolated, sharply defined cords with which the skill of the prosector presents us in museum preparations. The occasions are not many when exploration of the knee-joint becomes necessary on account of serious injury, if lesions of the semilunar cartilages are excluded, but such occasions call for the exercise of the finest judgement based on full experience. Radiography is a *sine qua non* in all doubtful cases, but it is of little positive help if there is no gross injury of bone. It may exclude such injury, but it can tell us nothing of the actual state or relations of fibrous tissues or cartilage. Unfortunately, despite its great range of movement, the knee-joint does not offer itself freely to inspection. It cannot be laid widely open without the infliction of an unjustifiable amount of damage, so that only a small part of it can be inspected at a time. The obvious graver injuries of the knee are bound to attract due notice and care. It is the slighter case of traumatic synovitis which may get the practitioner into trouble if not properly treated at the outset; for if, from lack of accurate diagnosis and early treatment, adhesions are allowed to form and are not broken down by the surgeon, the bonesetter may score a triumphant success and all the really effective part of the surgeon's treatment be ignored to his detriment.

There would seem to be in some people's minds an unconscious mental association between the idea of a damaged knee and of a spirituous solution of iodine. The sight of a knee the skin of which has been hardened and stiffened by the application of tincture or liniment of iodine is still too familiar, and the patient is too often in a position to aver that this irritating fluid has been repeatedly applied under "doctor's orders." In the most emphatic manner possible we second Mr. Fairbank's condemnation of the abuse of this application, which at the best is useless in such cases, and may be mischievous. Here, as indeed throughout his lecture, the advice given is practical and sound, embodying the results of long experience and keen observation. There is much truth still in the saying, often on the lips of a surgeon of the past generation: "Surgery is made up of anatomy and common sense."

THE PUBLIC ASSISTANCE ORDER.

THE Poor Law Order[1] with which we dealt in a leading article three weeks ago (*Journal*, March 8th, p. 453) has now been issued by the Minister of Health, but not without appropriate modifications and accompaniments. Our main criticisms fell under two heads —first, that the Draft Order placed the medical officers in an entirely improper relation with the lay officials of the county council and county borough council and ignored the medical officer of health, and secondly, that, as is now practically admitted, "the administrative picture drawn by the Order could not be reconciled with the line of development of policy which was accepted by Parliament when the Local Government Act, 1929, was passed." In the Order as now made the regulation that "the public assistance officer shall supervise and control in the performance of their duties all officers and servants engaged on Poor Law functions" (including, of course, medical officers) has disappeared, and instead the medical officer of health of the area comes into the picture as the officer "who shall advise the council on public health and other medical questions arising in connexion with the discharge by the council of their Poor Law functions." This is a radical amendment of the greatest importance, and there are a number of minor amendments in the Order all tending in the same direction.

In the Memorandum (Circular 1095) which accompanies the Order the Minister now makes it clear to authorities that the Order is issued for administrative convenience only, and that at a relatively early date it will require considerable modification. The Minister "proposes to discuss modifications with representatives of local authorities as soon as circumstances admit of the work of discussion being effectively done." Further, "the Minister desires that local authorities should be in no doubt as to the lines on which he would earnestly hope that development should take place. He regards the policy of transferring responsibility for the Poor Law to the county and county borough councils as being the first step in the process of breaking up the Poor Law, and particularly as placing the responsibility in question in the hands of authorities who have powers of prevention as well as of relief, especially in regard to the large mass of destitution arising out of sickness or invalidity. The determination of such matters by the authority in every area will inevitably raise administrative questions affecting medical issues of great practical importance. These issues will no doubt receive careful consideration by local authorities, and the desirability of making use of the accumulated knowledge and experience of the medical profession in regard to them will be fully borne in mind by those authorities." This constitutes a warning and advice which will be regarded by the medical profession with much satisfaction.

To emphasize and reinforce the position thus taken up, the Minister, in an appendix to the Memorandum, gives certain extracts from the important General Circular 1000 issued by his predecessor, and, as was suggested in our former article might well be done, he adopts and sets out some extracts from the annual report of the Chief Medical Officer of the Ministry for the year 1928. It is to be hoped that the fullest attention of the members of county and county borough councils and of their public health and public assistance committees will be directed to this appendix. It presents to them a picture of their opportunities and duties which is far from implicit in, if it is not contradictory to, that presented in the Order itself. The appendix embodies the spirit of the future; the Order, in the main, merely states the observances of the past. The position and functions of the medical officer of health are given due prominence. He "will be the chief medical adviser of the authority and its various committees in all matters relating to the co-ordination and general medical administration of the public health services (including all transferred services) provided by the authority under whatever committee they may be administered. . . . He will also be required to supervise, though less directly, all the medical services of the authority. In this duty it is important that he should intervene as little as possible between any medical officer employed for clinical duties and the patient whom that medical officer is treating." Further, the need for continuous consultation between the authority and the medical profession is clearly stated. Section 13 of the Local Government Act makes such consultation statutory in regard to hospital provision and usage. The Minister attaches the greatest importance to the carrying out of this section, and says, "It is imperative that local authorities should establish the most cordial relations with the medical profession in regard to hospitals. It is the confident hope and expectation of the Minister that as procedure under Section 13 becomes established and regular it may lead to wider arrangements for the fullest consultation between the local authority and the medical profession, not merely in regard to institutional accommodation and its use, but also in regard to those numerous developments in the health provision of the people which are implicit in the new organization laid down by the Act."

The intention of the Minister is that the Order and the accompanying Memorandum should be read together. If this is done the resulting impression is likely to be helpful, even stimulating, and the Order itself may do little harm. Our main regret is that the two documents are not bound up together so that it would be impossible for anyone to be in possession of the Order without at the same time having the Memorandum before him.

JUBILEE OF THE OPHTHALMOLOGICAL SOCIETY.

THE Ophthalmological Society of the United Kingdom celebrates next week the fiftieth year of its existence. It owed its origin to a small band of distinguished ophthalmic surgeons who were in the habit of meeting informally at Moorfields. The inaugural meeting of the society was held in February, 1880, at the house of Sir William Bowman in London, and its first ordinary meeting was held on June 23rd of that year. Sir Thomas Barlow, one of the members of the committee which originated the movement, has undertaken to respond to the toast of the society at the jubilee banquet on April 4th in the Fishmongers' Hall. The first council of the society included many others who had already or who later achieved renown in the world of medicine. George Critchett, Jonathan Hutchinson, Hughlings Jackson, and Henry Swanzy were vice-presidents, Nettleship and Stephen Mackenzie were secretaries, and Gowers, Brudenell Carter, Hulke, Henry Power, and Waren Tay were members of the council. Of the 114 original members of the society eleven still survive. Unfortunately, distance and the physical infirmities of age will prevent most of them from attending the celebrations, but Sir George Berry and Mr. J. B. Lawford have both promised to come, and with Sir Thomas Barlow, will represent the founders. The forty-nine published volumes of the *Transactions* prove how fully the society has borne out the aspirations

of Bowman's inaugural address. Thus in the first volume appears Waren Tay's description of the disease now known as amaurotic family idiocy, and the admirable account of optic neuritis in cerebral lesions by Hughlings Jackson: indeed, every volume contains papers of importance which have contributed to the advance of knowledge. The Bowman Lectureship was instituted in 1885 to commemorate the first president, and the first lecturer was Hughlings Jackson. Many men of great distinction have succeeded him, and this year Sir Arthur Keith will lecture on Friday, April 4th, at 5 p.m., on the genius of Sir William Bowman. In 1912 the question arose of amalgamation with the Royal Society of Medicine, and for some time the fate of the society was in doubt. But it was felt by many that the tradition of good work which had been built up by the society might be lost if its identity were merged in the greater society. The decision taken then has proved a wise one. The society made itself responsible for running an annual congress and agreed to leave the monthly meetings to the Section. That arrangement has resulted in building up a strong Section of Ophthalmology in the Royal Society of Medicine: and the Ophthalmological Society, despite the fact that it has budded out into numerous offshoots, is itself now stronger than ever, and works in complete harmony with the Section. A number of distinguished foreign ophthalmic surgeons are attending next week's congress as guests of the society, and the Royal College of Surgeons is holding a reception on April 3rd. The president of the congress is Mr. Leslie Paton.

"PREVENTIVE MEDICINE."

IT is highly desirable to get a clear idea of the connotation of the words "preventive medicine," especially as they are now being used as the title, or as part of the title, of a number of books or publications. Preventive medicine certainly should not nowadays be regarded as synonymous with public health, though it is still too common to speak of the sphere of the private medical practitioner as that of curative medicine and the sphere of the public health medical officer as that of preventive medicine. Neither spheres nor practitioners can be delimited in this way. Certain other connotations, though each may perhaps be justified in its place, cannot be regarded as any more rational if intended to be definitive or mutually exclusive. Thus, early treatment of disease may be described as preventive medicine. So may prophylactic treatment by vaccines or serums, or other measures, when there has been exposure to infection or when there is immediate liability to such exposure. So may the teaching of personal, domestic, school, workshop, and public hygiene by whatever agency; and so may an even wider inculcation of lines of conduct, prudential or moral, whether by doctors, by religious teachers, or by others. It is better to recognize that there is, in fact, no such entity as preventive medicine, but that there are preventive aspects of medicine. It is probably true that to these aspects not sufficient attention has been given in the teaching of medical students, and that, in consequence, they do not occupy the field to which they are entitled in the mind and work of medical practitioners. Some seven or eight years ago the General Medical Council directed the attention of teachers and examiners to the importance of this matter, and the advice then given, and since powerfully reinforced by the Chief Medical Officer to the Ministry of Health, is no doubt beginning to bear fruit. It may yet be doubted whether textbooks specially devoted to these preventive aspects are really needed. What is wanted is the pervading of the whole teaching with the preventive idea rather than its specific and separate exposition. Among recent publications is an *Outline of Preventive Medicine*,[1] issued in England by the Oxford University Press, but prepared by an editorial committee composed of Drs. F. E. Sondern, C. G. Heyd, and E. H. L. Corwin, under the auspices of the *New York Academy of Medicine*. It is a handy volume, well printed, and with a flexible binding, which medical practitioners and students may find convenient and useful. Yet it definitely suffers from some of the confusions, ambiguities, and difficulties above referred to. It begins with an article on the periodic health examination, and ends with one on self-medication, illegal practice, and drug addiction. In between are a number of chapters dealing seriatim with the different branches of professional work and the various specialties. Some of them are not easily distinguishable from short and somewhat superficial accounts of medical or surgical conditions dealt with more satisfactorily in the usual books on medicine and surgery. In others, though there is generally some attempt to relate them to the title of the work, it is clear that the author has not made up his mind exactly as to the most advantageous method of setting out the preventive aspects of his subject. One of the most successful perhaps, as might be expected, is the article on "Pediatrics." Here the opportunities for prevention are more definitely envisaged. This collection of special articles is not without its value, but, as the editorial committee say in their introduction, "Keeping people well is fundamentally the task of the general practitioner. He is better able to do this than are groups of specialists associated for the purpose, as there are other things that influence health in addition to the physical condition of the body, of which he is more apt to be aware. The general practitioner should school himself to this relatively modern task."

WINNIPEG MEETING, 1930: SECTION OF OTO-LARYNGOLOGY.

A PRELIMINARY programme has now been drawn up for the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association in Winnipeg at the close of August. The president of this Section is Sir StClair Thomson. A discussion on the early diagnosis of septic infection of the lateral sinus will be opened by Mr. Francis Muecke (London) and Dr. James T. Rogers (Montreal). A discussion on treatment of paranasal sinus suppuration, persisting after operation, will be introduced by Dr. Perry G. Goldsmith (Toronto) and Mr. A. J. Wright (Bristol); and Mr. Lionel Colledge (London) will open a discussion on the diagnosis of cancer of the larynx. The honorary secretaries of the Section (Dr. R. Scott Stevenson, 137, Harley Street, London, W.1, and Professor George W. Fletcher, 215, Medical Arts Building, Winnipeg) will be pleased to receive the names of members prepared to take part in one or more of the discussions, or to contribute papers, preferably dealing with one or other of the subjects chosen. A number of oto-laryngologists have arranged to sail from England on August 8th, and those who have not already arranged their passages are advised to do so as soon as possible. Particulars of the journey to Canada and of various alternative tours can be obtained from the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, W.C.1.

DENTAL SEPSIS AND SYSTEMIC DISEASE.

IN an address to the Odontological Section of the Royal Society of Medicine, on March 24th, Sir William Willcox recalled that seven years ago he had opened a discussion on the same subject—dental sepsis—before the same body. In a brief retrospect, he said that until 1900, when dental sepsis as a powerful etiological factor in systemic disease was first brought to the notice of the medical profession by Dr. William Hunter, it was not generally realized

that dental sepsis was the cause of the other diseases now recognized as being due to it. Indeed, the opposite view appeared to prevail—namely, that diseases of the teeth and gums were rather a result than a cause. The clinical experience of careful observers all over the country during the past seven years had strengthened the view that dental sepsis had far-reaching effects, and might be responsible for many diseases previously thought to have no connexion therewith. As to the mode of action of dental sepsis, Sir William Willcox said that there might be direct local infection of other organs; for example, the tonsils and nasopharynx might be infected by micro-organisms from the diseased periodontal tissues. The second mode of action was by blood-stream infection, giving rise to conditions of toxaemia or even acute septicaemia. The effect on the patient suffering from dental sepsis depended on the nature, rate, and amount of toxic absorption, and also on his immunity to the absorbed products of infection. The virulence of the organisms varied greatly, a fact which illustrated the importance of commencing with very small doses when vaccine treatment was being given. The resistance of a person to a dental infection might be broken down by constant dosing of the blood stream with toxic products from a focus of infection, whereupon a condition of sensitization resulted, and marked bodily reactions might follow comparatively small doses of the toxin. When sensitization existed, the first step in treatment was the removal, if possible, of the focus of infection. An additional measure recently tried with success in some cases under his care at St. Mary's Hospital was the intravenous injection of small quantities (10 c.cm.) of immunized blood every three or four days for about five doses. Afterwards an autogenous vaccine could be tolerated in small and gradually increasing doses at intervals of five to seven days. The immunized blood was obtained by inoculating a healthy donor of suitable blood group with the autogenous vaccine of the patient. Immunity, however, was fickle; a slight cause might transform a condition of apparent health to one of acute illness. Overwork, too great physical exertion, an injudicious dosage with vaccines, and many other causes might break down completely the immunity of a patient. Symbiosis had an important bearing in relation to the effects on the immunity; thus, while a patient suffering from dental sepsis remained in apparent health, some additional toxic factor resulting from an intercurrent infection might cause marked systemic effects. Clinical examination of the teeth and gums was the first step in determining the presence of dental sepsis. Every patient suffering from any illness which resembled that due to systemic effects of dental sepsis should have a radiographic examination of the teeth. Attention had been drawn to the occurrence of secondary infections as the result of direct transference of organisms to the nasopharynx or the alimentary tract. In cases under his care at St. Mary's Hospital it had been found that in about 90 per cent., where dental sepsis had existed for over a year, there was evidence of the presence of similar organisms in the intestinal canal. No doubt the tubular glands of the intestine became infected and carried on the process. Secondary infections might continue the infecting process after the dental sepsis had been removed, and they required treatment, otherwise the systemic effects of the original condition might fail to show improvement. Where dental sepsis was present the offending teeth should be removed, but the condition of the patient called for the utmost care in this procedure. [illegible] 1928. [illegible] it was wise for only one or two [illegible] of the immunity was lost, [illegible] patient being kept in bed under [illegible] teeth to be removed, the [illegible] pyaemia and severe systemic [illegible] observation. Sometimes [illegible] waited for an interval of two or [illegible] action resulted; this occurred [illegible] another extraction was done; the [illegible] three weeks [illegible] in such cases and very few teeth should be removed at a time. He had on several occasions seen a fatal septicaemia and malignant endocarditis follow extraction of infected teeth in a patient in poor health with low immunity. In cases of this type, where extractions were imperative, the patient should be kept in bed until the operative treatment was completed. In elderly people resistance to infection was often low and the power of tissue repair poor. In such cases extractions should only be carried out when really necessary, and the utmost care in procedure was required. He strongly condemned the extraction of teeth without adequate evidence that they were the causal factor. Sir William Willcox ended an interesting and very practical address by summarizing his general conclusions as follows: Dental sepsis is the commonest focus of infection in the body, and must be regarded as one of the principal sources of disease of adult life. By reason of the great advances in medical and dental knowledge it can be diagnosed with accuracy, and a decision as to its causative effect in various diseases can be gauged. The dentist, with whom must rest the final decision as regards extractions, plays a most important part not only in the essential treatment of common prevalent diseases, but in the prevention of the many illnesses that may arise from untreated dental conditions.

HEATING AND VENTILATION IN SCHOOLS AND FACTORIES.

THE Industrial Health Research Board has published the results of an inquiry by Dr. H. M. Vernon and Mr. T. Bedford (assisted by Mr. C. G. Warner) into several new systems of artificial heating and ventilation that have recently been adopted by schools in different parts of the country.[1] Its purpose was to determine how far these systems could be recommended to factories and industrial establishments whose methods were described in two previous reports. The investigations were concerned with under-floor heating and panel heating, and with various degrees of open-air and semi-open-air ventilation. Studies of panel heating in large offices and buildings had indicated that the system was very suitable for factories, because it maintained an almost uniform temperature at all levels. Data, however, were lacking in regard to its physiological effects. The system of under-floor heating has been adopted by only a few elementary schools in this country, but it seemed probable that such a method would increase the comfort and efficiency of workers by raising the temperature at foot level instead of at head level, which had been found to be the effect of most of the systems in general use. Tests were carried out in various types of schools, including those held wholly or partly in the open air. A common criticism of the open-air schools is that in cold weather the children attending them are unable to work as efficiently as those in ordinary heated schools, and, since in these circumstances parents prefer to keep their children at home, there is a marked irregularity in attendance. This objection is sustained by the report which states that pupils in unheated open-air schools worked on an average only half as well in cold weather as those in heated schools, even when provided with extra food and clothing. From a series of experiments designed to ascertain the relation of temperature to manual dexterity it appears that the temperature in schools must not be less than 55° for efficiency in manual work, such as drawing and writing. A survey of three years' absences of 6,312 children attending 26 schools showed that the number was lowest (7.6 per cent.) at ordinary schools with good cross ventilation, and highest (10.2 per cent.) at badly ventilated schools. At unheated open-air schools during a period of very cold weather only half of the children

[1] Medical Research Council. Industrial Health Board. Report No. 58. A Study of Heating and Ventilation in Schools. London: H.M. Stationery Office. 1930. 2s. 6d. net.

were present. It is suggested that a system of under-floor heating would help to solve this problem more economically than any other. A panel system, where heat is radiated from the ceiling, is not considered to be effective for the open-air school, but it is regarded as preferable for most other purposes. Either of these methods can be employed in the semi-open-air school without diminishing the degree of air movement induced by open doors and windows. The advantages of the semi-open-air principle would also be increased by a careful regulation of doors and windows, so as to equalize the cooling power of the air to which the children are exposed. Both methods distribute heat more evenly than hot water pipes or radiators, and the apparatus is more compact. Whether under-floor heating would be suitable for factories is thought to depend partly on the nature of the machinery used and partly on the amount of unoccupied space. In workrooms where most of the floor is exposed, and where the machinery is light there is evidence that such a system would be successful especially if installed in draughty rooms with big doors that were often open to the air. Semi-open-air ventilation is obviously unsuited to many industrial processes.

A MEMORIAL TO LAMARCK.

JEAN BAPTISTE LAMARCK, soldier, biologist, and philosopher, was born in Picardy in 1744, and died in 1829. His remains lie buried in an anonymous grave in Montparnasse cemetery, Paris, but until 1914 his native country had a memorial of him in the house where he was born, the home of his ancestors at Bazentin, a small village of the Somme, not far from Albert. During the war years Bazentin lay within the war zone, and now what was Lamarck's house is but a heap of ruins. The Société Linnéenne du Nord de la France has resolved to raise a fund to be used for the purpose of erecting on the site of the old house a memorial worthy of Lamarck's greatness. This memorial will stand in the middle of a garden in which the plants grown will be the botanical species specially studied by Lamarck or named after him by other botanists. Lamarck belongs not only to his own province and country, but to all countries whose culture has been influenced by his pioneer work; and the Société feels, therefore, that to help it in its project it may call on the members of the great scientific brotherhood throughout the world. It extends its appeal to the scientific societies of the British Isles, and asks that all remittances by cheque or international postal order should be directed to the account of the Société Linnéenne at the Banque de France, succursale d'Amiens (Somme), and ear-marked for the Lamarck Fund. Letters should be sent to M. le Secrétaire Général du Comité Lamarck, 81, rue Lemerchier à Amiens, Somme.

NATIONAL INSTITUTE FOR THE BLIND.

DURING the last fifteen years the National Institute for the Blind has done meritorious work as a co-ordinating centre for the support of numerous local societies throughout the country. The financial aspect of this policy was more recently defined in a unification scheme by which resources derived from one appeal in a specified area were allocated in agreed proportions for local and national purposes. During 1928–29, according to the sixtieth annual report of the institute, collecting agreements increased from 57 to 79, but the effort to secure a wider and more equable distribution of service resulted in a decrease of £7,000 in the annual income. Allocations and grants amounted to £21,739. The general activities of the institute are too familiar to require detailed comment here, but several notable achievements were accomplished during the year. It was an appropriate circumstance that the institute was able to publish a completely revised catalogue of its books in the centenary year of the invention of Braille writing and printing, and to ensure that a Braille edition shall be published as a guide to literature for the blind. Books in this catalogue are supplied to every blind person residing in the British Isles and in the British Empire at a discount of two-thirds of their cost of production. A new series of embossed maps of all countries is in course of preparation. Seventeen periodicals, including a massage journal, are published by the institute; three of these are embossed in Moon type. Not less remarkable was the progress in music. In future blind musicians of every nationality will be able to read and understand a piece of music, wherever published, in modern Braille notation. This uniform system, based largely on that of the institute, was devised by an international congress held in Paris for the purpose last spring. While expressing satisfaction with these alleviatory measures the report emphasizes that the most serious and urgent problem at present is the employment of the blind. A special committee has been appointed to collect data on the subject from all parts of the world. Its chief purpose is to find occupations for blind workers outside those commonly practised, and to place them in industries hitherto ignorant of their qualifications. The committee is co-operating with an appointments board and with the National Institute of Industrial Psychology, which is making a special study of blind workers and of the industrial problems affecting them. It has often been suggested that massage is the ideal profession for the educated blind of both sexes. At the institute's school of massage, medical gymnastics and medical electricity arrangements are made for resident students to lead a normal and communal life in hostels. This department not only provides training but deals with the settlement of students and protects their professional interests.

PSYCHIATRIC PROBLEMS IN GENERAL HOSPITALS.

IN a paper recently published in the *American Journal of Psychiatry*[1] Dr. George W. Henry, senior physician to the Bloomingdale Hospital, New York, illustrates by means of a number of interesting cases the errors that are likely to arise from the neglect of psychiatric consultations in general medical and surgical practice. He cites as an example the case of a young Russian Hebrew who, in the course of an illness of two and a half years' duration, was admitted to ten different hospitals, and treated in seventeen different dispensaries and by six different private physicians. In his search for relief he had been told at different times that he had bronchitis, pulmonary tuberculosis, gastric ulcer, chorea minor, cardiospasm, intestinal obstruction, nephrolithiasis, post-operative adhesions, and an abdominal tumour. Each hospital and physician, unaware of previous observations, undertook the usual diagnostic procedures, and after many examinations and tests arrived invariably at the conclusion that the illness was some form of psychoneurosis. In the meantime, the patient was made incalculably worse by the frequent examinations, discussions, and opinions. He lost 20 lb. in weight and became totally invalided and unwilling to accept any diagnosis but his own. He now insisted that if he was "nervous," it was because physicians had failed in their treatment of his physical illness. In such a case, in Dr. Henry's view, the repeated physical examinations and the many tests for physical disease were not only unnecessary but distinctly harmful. They continually directed the attention of the patient to localized bodily complaints, and caused a serious delay in the application of appropriate treatment. The patient's unusual ability to mislead physicians who lacked psychiatric training was also a complication in that he could at any time find another

[1] Vol. ix, No. 3, p. 431.

doctor who would continue the search for a possible physical disease. On the other hand, if psychiatric knowledge and experience were more generally in the possession of the medical profession, the nature of the illness in a case of this kind would be promptly recognized through its own peculiar manifestations. Dr. Henry complains that even in the best medical schools the teaching of psychiatry is inadequate, some of the classes being conducted under the direction of older physicians and surgeons who obtained their own acquaintance with the subject from a few lectures and demonstrations given at a "hospital for the insane." In these circumstances it is not surprising that among 300 cases studied intensively there was only one history indicating that the writer had a fair grasp of psychiatry. It is, in Dr. Henry's view, futile to relegate this work entirely to specialists, for it is doubtful whether there will ever be a sufficient number of psychiatrists to respond to all the requests for consultations. There is, he believes, no alternative to educating general physicians in the elements of psychiatric methods, and he makes the following recommendations, based on his varied experience with the psychiatric problems in the wards and out-patient clinics of general hospitals. Every general hospital should have a psychopathic department and at least one attending psychiatrist. Except in emergencies no eccentric or neurotic individual should be submitted to an operation or started on a prolonged course of treatment without psychiatric consultation. No medical student should be permitted to graduate without having taken a course in the psychiatric aspect of general hospital practice, and a period of study in a psychopathic hospital should be a part of all hospital internships. In giving psychiatric instruction the emphasis should be placed upon the less obvious disorders which so frequently complicate general medical and surgical practice, while the well-developed psychoneuroses and frank psychoses should be studied chiefly for the purpose of giving perspective. All staff conferences in general hospitals should be attended by the psychiatrist so that there might be a mutual exchange of medical experience and frank discussion of those cases in which there are psychiatric problems.

A NEUROLOGIST'S ROMANCE.

THE name of Dr. E. Feindel of Paris, whose death took place on January 19th, is known to neurologists all over the world, but we doubt if many outside his own country are familiar with the story of his life which is told in a sympathetic obituary notice in the January issue of the *Revue Neurologique*. About thirty-five years ago he was *picked up comatose in a Paris street and taken to* the Hôpital St. Antoine. On recovering consciousness he was found to have right hemiplegia. The late Professor Brissaud, under whose care he was placed, found that though no improvement was likely to take place in the hemiplegia, the intelligence and judgement were intact. The patient turned out to be a well-educated man who had obtained a science degree at Lyons University, and was earning a moderate living as a tutor in Paris. Brissaud encouraged him to write with his left hand, gave him some work in his laboratory, entrusted him with some bibliographical research, and finally persuaded him to qualify as a doctor. Feindel's inaugural thesis on neurofibromatosis[1] was a richly documented work which can still be consulted with profit by those interested in the fascinating subject of von Recklinghausen's disease. Being unable to practise he devoted himself to literary work, and in addition to acquiring the knowledge of several foreign languages, taught himself shorthand and the use of a typewriter. During the whole of his professional life he was closely associated with the *Revue Neurologique*, to which he contributed numerous original articles and summaries of current literature in many languages, as well as being responsible for the excellent table of contents and bibliographic files. He was the author of a series of important articles on gigantism, infantilism, paramyoclonus, and "spondylose rhizomélique." The work on ties and their treatment which he wrote in collaboration with Henry Meige was translated into English by Dr. S. A. Kinnier Wilson in 1907.

NATIONAL COUNCIL FOR MENTAL HYGIENE.

THE seventh annual general meeting of the National Council for Mental Hygiene was held at the House of the Medical Society of London on March 21st, under the presidency of Sir MAURICE CRAIG.

Lord SOUTHBOROUGH, the treasurer, in presenting the report and accounts, said that, although still in need of money, the council's finances were in a better condition than in previous years, as there was a bank balance of about £440.

Dr. J. R. LORD, one of the honorary secretaries, gave some account of the council's activities, which, he said, had not *been spectacular, but sound. The work already done through* physicians and officers of the established services for the treatment of mental disorder was fully recognized, and the council existed to co-ordinate all the forces directed to the promotion of mental hygiene. Apart from the insane and the mentally deficient, there were large numbers of people handicapped by minor mental illness; to study the root causes and to help the sufferers was a problem which the council had set itself, through committees and by means of experts. Reports had already been forthcoming which were highly valued. He went on to narrate the steps taken by the council in connexion with the Local Government Act. An open letter had been sent to all local authorities and medical officers of health urging the need for early treatment of mental disorder among the poor, for which opportunities were afforded under the Act, and he had proof that the suggestions of the council had been received most sympathetically. A report on the Mental Treatment Bill had been circulated and had received every consideration from various local authorities. He also referred to the interest of the Mental Health Conference held in the autumn of last year (and fully reported in these columns), and to the forthcoming First International Congress of Mental Hygiene, to be held at Washington next May, which would be attended by Sir Maurice Craig. *Magnificent work had been done in America on the study of* these problems, and the congress would stimulate still more.

The CHAIRMAN spoke in warm praise of the staff of the council, especially the two honorary secretaries, Dr. J. R. Lord and Dr. R. D. Gillespie, the treasurer, Lord Southborough, and the honorary organizer, Dr. Doris Odlum. The report was adopted, and the retiring members of the committee were re-elected.

Dr. DORIS ODLUM reported on the autumn series of lectures on mental hygiene subjects. These lectures, which were of a popular character, had evidently met a real need, and a spring course was now being given.

Some discussion took place on a remark made by Lord Brentford on opening the Conference on Mental Health—namely, that attempted suicide was always the outcome of mental disease. This view was combated by some members at the meeting. Sir MAURICE CRAIG pointed out, however, that "mental disorder" must not be regarded as synonymous with insanity, and Dr. LORD said that all Lord Brentford had done was to point out that the largely increasing number of suicides or suicidal attempts were indicative of failure to take steps to secure early treatment. He thought it was not sufficiently kept in mind that mental hygiene had two divisions —a positive and a negative. It was the positive side of mental hygiene which was often forgotten—namely, the improvement and usefulness of the mind. Negative hygiene was the prevention and cure of mental deterioration. In America positive mental hygiene was carried on in schools by educational methods—some of which might not be approved in this country, as they might be thought to invite a morbidity of outlook.

The meeting closed with a vote of thanks to Sir Maurice Craig for presiding.

PSYCHOLOGY AND THE PRACTICE OF MEDICINE.*

BY

J. CAMPBELL McCLURE, M.D.,

PHYSICIAN TO THE FRENCH HOSPITAL, LONDON, AND TO THE MARGARET STREET HOSPITAL FOR CONSUMPTION.

I HAVE *chosen the subject "Psychology and the practice of medicine" with the intent to show that the medical practitioner is faced every day with problems largely psychological in their nature, and that a greater knowledge of such problems is becoming more and more necessary to him if he is to preserve his place in an advancing world. I would ask you to look upon psychology as the study of personality. The psyche was in earlier days considered to be that part of the mind which was occupied with intellectual and emotional registration and expression, and there is no reason at the moment to dislodge it from that position. Personality grows and expresses itself through intellectual and emotional stimuli and reactions, which may arise from within or from without the person. Such stimuli and reactions are conveyed and expressed through the medium of agencies which we are accustomed to call somatic—such as the organs of special sense, the skin, the neuro-muscular and neuro-secretory systems, and the various nerve centres. The formation and expression of personality depend on a proper response to stimuli of large groups of cell communities more or less in touch with external influences, and also on processes generated and carried out entirely by the higher centres in the brain and their communicating fibres. Therefore, in the study of personality we are faced at once with the fact that a response to stimulation may be altered in some way by faults in any one of the transmitting or registering systems involved.*

A stimulus may fail to register in the brain through a fault in the skin or in one of the more highly specialized sense organs. Again, a stimulus may reach the brain quickly but may fail to produce a reaction either on account of the incapacity of the higher centres to appreciate it, or because some fault in the efferent mechanism prevents its translation into appropriate action.

The normal effect of introducing a pin into the skin is to produce a sensation of pain. This sensation ought to have the effect of causing the person to remove the irritated part of his body from the pin. Again, if the skin of the face is slapped by an alien hand, the usual reaction is a local discomfort and flushing, and a rapid translation of the stimulus into violent muscular action of a retributive character. Here the stimulus has been more complex. The true personality has been attacked and an emotional response is induced, as well as a mere somatic sensation and reflex. Where intellectual power is weak the emotional response will occur with certainty; so that if you slap the face of a person of small intellectual and at least average emotional equipment, you may expect to be severely dealt with. In our comparatively civilized communities, however, such a "normal" reaction is inhibited by training and experience, and if the face of a really well-trained man were slapped in a drawing room, the usual neuro-muscular response would not occur. In all probability the emotional reaction would be registered externally by a generalized pallor, against which the local flushing would stand out strongly, by a clenching of the hands and a general rigidity, the result of the central effort to control that is part of the training of all civilized beings. This control of impulses for the good of a community is one of the most important features in psychology. In anything like completeness it is not inborn; it has to be developed. In personalities that have behind them a reasonable history of racial and familial civilization, the training and development are not very difficult; the response to instruction and to experience is rapid, and memories are readily formed which act as a check when the period of instruction is past. The development of control must be the result of an understanding that we are responsible, in a community's life, not only for our own welfare but also for that of other people. No person's psychology is properly developed unless emotions, and their natural expressions, are controlled within safe social limits, and a sense of duty to other people is properly developed.

Human beings live in an environment that is continually changing, and it is impossible that all can develop adaptive qualities in the same degree. Sense stimuli grow more and more urgent—noise, hurry, the adaptation of the mind to newly invented things, all go to form an environment which is very trying to the psychological make-up of all of us. Some personalities respond to these stresses and changes with little apparent effort; some grow confused and dull; others are so sensitive to the ever-increasing stimuli that their responses seem to get beyond their capacity for control, and they become restless, excitable, and in the end exhausted. Even among those who apparently adapt themselves easily there are many whose capacity for control, although enough to cope with the stimuli of their ordinary life, gives out under strain that is abnormal to them, whether sudden or prolonged, emotional or intellectual.

The preservation of a just balance between emotion and intellect is a psychological necessity if a personality is to develop along the lines of greatest service to itself and to others. The uncontrolled emotional person is no more abnormal, and often not more disturbing to a community, than the cold and over-controlled intellectual who by nature or training appears to have developed a complete immunity to the attack of all emotions. The inhibition of natural emotional reactions can be carried to excess, especially if it is merely active in preventing an obvious response to a stimulus, and not also active in correcting the thought-response, so that the following reaction may be harmless, and even beneficial. The most obvious example of how the control of only external expressions may be of poor service to a personality is met with in the response to sex stimuli. If control is exercised merely to prevent a ready expression of the reaction, sooner or later the personality will develop abnormalities of reaction, especially if the control is induced by fear of personal consequences and not by a true sense of responsibility. On the other hand, if in response to sexual stimuli, control is exercised not only in the direction of repression but to convert the emotions aroused into higher forms of expression, the resulting reactions may be of the most elevating kind. Many of mankind's greatest achievements have been without doubt the result of the harnessing and translation of human passion. Control should be so developed that not only the repression, but the useful development of emotional reactions shall be the result.

Control is difficult to develop in certain instances for two reasons: through inborn faults it may be weak, so that it gives way under a very small strain; it may be considerable and yet be overcome by an excessive response to a specific stimulus. Many people give way through sheer weakness of control to ridiculously small stimuli; others, whose general control is at least up to the average, succumb to emotional appeals which to them are strong enough to be almost irresistible. In the latter class are to be found many of those who become alcoholic. Naturally hypersensitive and shy, regarding too much the opinion and power of others, they use alcohol to dull their sensitiveness, and to remove the principal barrier between themselves and those whom they wish to impress.

In medical practice by far the larger number of patients showing psychological weakness belong to this hypersensitive group, and it is the duty of the practitioner to try to discover how much of the psychological weakness is due to gross somatic causes before he tries to influence such a personality, whether by persuasion or by some more specialized form of psychological treatment. Chronic toxaemia, endocrine disturbance, combined with an inherent metabolic fault, may produce psychological aberrations so profound that the patient may appear to have crossed the border between sanity and insanity. In the treatment of such cases it is necessary to think at first along purely somatic lines. Only if no somatic disturbance is discovered, and organotherapy and drug treatment have failed, must the doctor turn to directly psychological methods

* Abstract of the annual oration delivered before the Hunterian Society of London on March 3rd, 1930.

of treatment. Somatic disorders, secretional, chemical, or toxic, have a profound influence on personality. This is not extraordinary when one realizes that all emotional and intellectual processes depend for their inception and development on a somatic mechanism, and if that mechanism is at fault on its nutritional, afferent, or efferent sides, the intellect and emotions will suffer. Phobias may be due to some psychological trauma, but among my own cases I have found in 70 per cent. a definite somatic fault which seemed to determine the occurrence of these fears, and with whose correction the fears disappeared. The sensation of fear is largely referred to the epigastrium, and accompanied by disturbed cardiac action, and observation has shown that these discomforts are associated with a dilatation of the gastric fundus. This type of gastric dilatation, with varying degrees of paroxysmal tachycardia, and epigastric and left hypochondriac uneasiness, was the somatic fault present in 70 per cent. of my cases of phobia, and it seems possible that the cardio-gastric phenomena associated with fear, if produced by other means, may suggest to the higher centres that the patient is afraid, with the result that he searches unconsciously for a cause, and unfounded fear of crowds, or open spaces, or personal failure ensues.

Children are not born with a highly developed faculty of control or sense of responsibility. They have to acquire our standards of right and wrong carefully, and in many cases with difficulty. A child is apt to put out his hand and take what he wants, having no regard for others, an instinct common to all primitive creatures. His instinctive reaction to fear is to lie, simply for self-protection. Only training and experience teach him that he must not take other people's property, and that lying is a social evil of some magnitude. In the majority of cases such instincts are corrected before the age of 12 or 14, but in a certain number of people a tendency to dishonesty and untruthfulness persists into young adult life, and may die only with the person. If parents and schoolmasters are honest enough to recognize that they themselves have had comparable difficulties, the cure of these tendencies is almost certain. The treatment must, however, be sympathetic and rational. Fear of immediate consequences is only a deterrent; hell-fire and flogging are merely repressive and not really educative agents. The dull or apparently irresponsible youngster may be cured by the correction of a physical defect, such as an error of refraction or an endocrine ill-balance, but the fault may be beyond the reach of such treatment, and yield only to careful training combined with suitable employment. Irritable and inattentive children may settle down to steady work when introduced to a subject which interests them and for which they have an aptitude. Moreover, as they grow in knowledge along one line, they may develop capacity in quite different kinds of work. Co-ordination of the fingers by means of a dumb piano may contribute to the cure of a stammerer; so the development of methods of learning produced by the study of one subject will promote educational success in others.

Those of us who during the war were interested in the re-education of the disabled were astonished to find the psychological improvement that often followed on an entire change of occupation, and how well some ordinary journeymen developed when a chance was given them to become foremen, buyers, or even managers.

Experimental psychology must appeal strongly to all of us who admire the methods of Hunter. I do not think that John Hunter, had he been alive to-day, would have busied himself only with the chemistry of protoplasm or refused to liberate himself from the tyranny of the microscope. Rather do I think that his restless mind would have been much occupied in thinking ahead of proved facts while insisting on proving as much as possible. In psychology experiment is as necessary as in any other field of knowledge, and facts about reaction times, for example, are of the utmost importance in the study of personality. A good observer can separate people into classes by finding out if their reaction times and association rates are average, fast, or slow, thereby establishing whether the relations between the sense organs, the centres, and the neuro-muscular system are normal or not; afterwards, perhaps, he will be able to state with some degree of accuracy whether the three systems are healthy, or where the failure has occurred. From the clinical point of view it is of interest to realize that, once such a classification is made, a capable medical man is able, by appropriate treatment, to raise many from lower to higher classes; but we must remember that to every individual is set a limit to his capacity for improvement, and that trying to improve the unimprovable is a waste of time. Practical psychology, with medical co-operation, could also be used for the grading of young people into classes suitable for different kinds of work, and much unhappiness and poor development, with their attendant train of sickness and incapacity, could be avoided, to the great financial betterment of this country.

To consider, however, that by the study of experimental psychology may be obtained the only means of recognizing and remedying psychological faults, would be as ridiculous as to decry its usefulness. There is still room for the thinker who, beyond his observations, can erect hypotheses on which good work can be done though experimental proof be still wanting. The metaphysician is as necessary as the physicist and the physiologist in the study of psychology. Facts without correlation, discoveries claimed as facts without adequate proof, experiments unchecked by reason, may be as useless and as dangerous as theories unsupported by facts. The way lies between the experimentalist and the speculative thinker. The usefulness of psychology to the medical man lies in his being bound neither to one wheel nor the other, but in his being carried by both to a practice equally useful to him and to those under his care.

There is need to-day for the sensible treatment as well as the differential diagnosis of psychological ailments. According to the diagnosis, so must be the treatment. It is futile to attempt to treat by psycho-analysis a disorder of personality due to an inherent endocrine weakness exaggerated by toxaemia of intestinal origin. Yet beyond the groups of psychoses of directly somatic origin, beyond the faults of character already indicated, there is a group or groups whose explanation is not so easy and whose treatment must be along special lines. I cannot believe, however, that even one-third of these groups contains sufferers from psychological faults that are due to sex repression and complexes named from various interesting characters in Greek mythology, but that they all need special therapy on psychological lines is certain; personality must be corrected in these cases by personality, whatever be the best and safest means to employ. Psychological injuries are as real as surgical injuries. Control, emotions, intellect, may all suffer as the result of some dreadful experience, physical or mental, and while it becomes evident that the balance of endocrine secretion and body chemistry is upset, one becomes impressed with the fact that those disorders are not primary and that some deeper injury has been sustained which has deranged the whole neuro-secretory system.

The study of such cases shows that all kinds of errors in thinking, feeling, and interpretation may occur. Wrong conceptions of life, exaggeration of ordinary sensation of the sense of pain, And misinterpretation of all sensations are among the most disturbing features of their sufferings which are very real. Perhaps the most interesting are those who misinterpret symptoms and attribute to malicious external agencies the effects of their physical disorders. All such derive benefit from overflowing to their medical adviser; and the fact that such conversation does help them indicates one of the most successful lines of treatment, a combination of the confessional and the consulting-room, by which the doctor can obtain information of psychological injuries and repression dating, perhaps, far back into childhood. The patient, having told the story, is frequently in a condition to be receptive of advice and reassurance. This can be done very well in most instances without resort either to complete psycho-analysis or to overt suggestion. In other cases, however, complete psycho-analysis or deliberate suggestion, either in the waking state or in a state of complete or partial hypnosis, seems to be necessary if a real improvement is to take place. In my experience the resort to psycho-analysis or to overt psychotherapy is not as necessary as has been urged by some; a perfectly good abreaction may be induced by ordinary sympathetic treatment by a medical man without pre-

he mud that exists in the unused memory of most of Later, an ordinary quiet but complete explanation that orts of sensations are natural and only harmful if they d shame or fear, or are elevated to a position in life of proportion to their importance, will in most cases he patient on better lines of thought, and remove worry dread. With this improvement will come also an im-ement in the general condition which can be hastened, the psychical difficulties are overcome, by suitable tment along more ordinary lines.

ie avenues by which wrong thinkers can be led back he normal are many. To some, the appeal for fairness thers, for "playing the game" domestically or socially, ough to correct their line of thought; to others, the al to their dread of being ridiculous is a strong in-ive to correction—ridicule is the most powerful weapon se against the Englishman. The removal of the idea they are useless has cured many; this line of treat-t often involves investigation into the patients' capacity inclination, and the training of them in suitable work, er as a hobby or as a means of livelihood. Some are roved by being encouraged to develop some means of ural emotional expression, like music or dancing. To y the emotional appeal and development must be along gious lines. It is not enough, however, to prove that a of thought is incorrect and foolish, to expel a devil and e the room swept and garnished. Successful psycho-apy demands not only the extrusion of wrong ideas, it ands their replacement by right ideas. The patient t not only be convinced that his attitude is wrong, but t be supplied immediately with a chart of right con-. On the hyper-selfish must be urged the need for the sideration and the service of others; on the shrinking t be urged the necessity for courage and the capacity achievement; on the dreamy and apathetic, the virtue ction; on the over-active, the value of relaxation and aming.

ae separation of the psychologically abnormal from the eral run of medical work can be carried to excess. Too h public discussion of the different kinds of neuroses psychoses, as a group of diseases curiously apart from nary ailments, is apt to encourage the development of e very abnormalities among the more unstable part of population. I think that since the death of Charcot e have been fewer hysterical manifestations of a major l in France; there have been fewer cases of the very lition in which that great man's treatment was so matically successful. In our day a great many lazy ple exist who before the advent of psycho-analysis ld have been treated with a little thyroid or some r suitable medicament and ruthlessly told to work out ir salvation in useful occupation, but now suffer from an iferiority complex," and thus demand the sympathy due mysterious psychological fault which requires treatment very special kind. Others would far rather have their stipation treated by a complicated system of dieting electrotherapy, reinforced, perhaps, by a course of hypnotic suggestion, than do what Winnie-the-Pooh "stoutness exercises" before breakfast, and walk miles every morning and afternoon. Some three sand years ago a court official called Naaman objected ngly to being advised to use as a therapeutic agent iver called Jordan, preferring the more magnificent bana and Pharpar, rivers of Damascus." The e psychology persists to-day, and the result is a espread conviction that better results can be obtained extraordinary than by ordinary means, many even ferring to seek advice outside the qualified group nedical practitioners, in the belief that there is a more ient group of healers whose practice is unhampered by much tradition and training. Irregular practitioners e sometimes great successes, and of these successes near much. The cured are only too willing to extol their cleverness in going beyond the poor old plantigrade lical profession, and discovering the virtues of an un-scribed Abana. But do we hear as much about the ures? Fear of the little words "I told you so" deters y from an open confession, and patients merely creep k; a little shamefacedly, to seek the ministrations of a fectly ordinary doctor. There is, however, something to be said in excuse for those who seek the aid of the irregular practitioner. We have been too rigid in the past, adapting ourselves too slowly to new advances in science, and I fear that only by the sedulous cultivation in our practice of sense and sensibility can we live down the reputation for pride and prejudice which we seem to have acquired.

RADIOGRAPHIC THERAPY OF STERILITY.

ADDRESS BY DR. LOBRE.

At a meeting of the London Association of the Medical Women's Federation, held on February 25th at the British Medical Association's House, with Miss FRANCES HUXLEY in the chair, Dr. FRANÇILLON LOBRE delivered an address on the radiographic therapy of sterility.

Dr. Lobre said that whereas the method of tubal insufflation merely showed whether the tubes were or were not permeable, radiographic examination with lipiodol revealed the situation of an obstruction impairing tubal permeability, which was a point of capital importance if reparative surgery was contemplated. The radiographic method also supplied information about the exact position of the uterus and its form; the appearance of the tubal and uterine cavities; and the condition of the mucosa and its reactions to lipiodol. Such examination showed the importance of uterine and tubal spasm in a large number of the cases, and thus afforded valuable indications for the treatment of sterility.

Lipiodol was well tolerated by the tubes. Rubin had described some cases in which the radiographic method was followed by peritoneal reactions, but it was possible that the cases of infection recorded had followed the use of a liquid other than lipiodol. Laparotomies had been performed upon women who had received injections of lipiodol forty-eight hours previously, and no sign of peritoneal inflammation had been encountered. In certain cases where mistakes in technique had permitted injections to be made under too high pressure, small collections of oil had been found in the connective tissues, but no sign of inflammation. It was necessary to keep the pressure under strict control, but with lipiodol the pressure employed might be higher (up to 30 cm. of mercury) than was permissible when air was insufflated (in this case up to 23 cm. of mercury). Gases, being easily compressible, might induce a pressure at the point of resistance higher than that at the point of escape, and it was therefore logical not to exceed an initial pressure of 23 cm. for insufflation, in spite of the fact that a much higher pressure was required to produce experimental tubal rupture.

In collaboration with Dr. Jean Dalsace, Dr. Lobre had examined 230 women for sterility during the last three years. The cases examined were those in which a preliminary examination of the husband had eliminated the male factor, and in which careful clinical examination of the woman had proved negative. Contraindications to radiographic examination were the presence of active lesions, such as those accompanying metritis, salpingitis, appendicitis, or metrorrhagia. The best time for the exploration was during the week following menstruation, from the fourth to the twelfth day. At this period adnexal reactions could be most effectively avoided; moreover, the risk of injecting during pregnancy was eliminated by choosing a time shortly after menstruation had occurred. The patient had to be prepared for the examination with the greatest care. It was necessary to be sure that the cervical orifice was permeable, since radiographic examination was never to be immediately preceded by dilatation of the cervix. The examination itself had to be made with the care and precautions adopted in all minor gynaecological procedures. In order to ascertain whether the tubes were or were not permeable, a second radiogram had to be taken a few hours after the first to discover if the shadow still remained in the tubes, or was disseminated in patches in the abdominal cavity. For the purpose of this second examination the patient remained in the hospital or clinic for a few hours before returning to her home.

The gynaecologist and radiologist had to collaborate in the examination, which was not painful. The only

disagreeable moment for the patient was when the cervix was grasped with the forceps, in order to close it, since the injections had to be made under pressure. The pressure employed was regulated with a manometer, and was *not allowed to exceed 30 cm. of mercury*. By prolonging the pressure sufficiently it was often possible to restore permeability to otherwise impermeable tubes. The examination should be made patiently, and without haste. The passage of lipiodol into the cervix, and then into the tubes, which it entered through the mechanism of the uterine contractions, was followed radioscopically on the screen. To avoid pain, said Dr. Lobre, she was in the habit of giving sodium bromide or benzyl benzoate for two or three days before the examination, and an analgesic suppository was introduced one and a half hours before the examination, which was immediately preceded by swabbing the cervix with a solution of novocain.

The opaque substance used was 40 per cent. lipiodol, rendered more liquid by warming on the water-bath. Many instruments had been devised for injecting lipiodol, that constructed by Dr. Lobre consisting of a cannula of very malleable nickel-plated copper, bearing a tip shaped like an olive, with a terminal orifice, and two large lateral eyelets. *The cannula bore a flattened shoulder, situated* 4½ cm. from the tip, designed to prevent it from passing too deeply into the uterus. At the other end of the sound there was a three-way cock, bearing two threaded tips. The metallic syringe was attached to one of the tips, while upon the other was fitted a sterilized tube containing a piston, attached to which was a manometer.

The patient was placed on the table lying on a draw-sheet, which enabled her to be moved easily. At the end of the table were two movable stirrups, which permitted her to be placed in the gynaecological position. The vagina was irrigated with an iodized injection, and the cervix then exposed by a bivalve speculum. It was swabbed with alcohol, and grasped with the tenaculum, to permit easy introduction of the metal sound. If the cervical os was large, it could be closed with a large forceps, *with the grasp directed backwards; if small*, it could be closed with the aid of one or two bullet forceps. The oil was injected slowly, at a pressure never exceeding 30 cm. Care was taken *not to permit reflux into the* vagina. The speculum was then removed, and the patient pulled into the middle of the table by means of the draw-sheet.

For radiography, the Coolidge or Philips tube was employed, one tube being beneath the table for examining radioscopically with the patient recumbent, and for making radiograms during the examination, a plate being placed on the abdomen. Radiograms were also made of the pelvis, both from the front and from the side. When the course of the tubes was masked by the uterine cavity an oblique exposure was taken. It was thus possible to take anterior or posterior plates without changing the position of the patient. The plates were developed immediately and before the sound was withdrawn. In this way the examination might be repeated, if it was not wholly successful *the first time. It was absolutely necessary to follow on* the fluoroscopic screen the intrauterine course of the injected lipiodol, to observe the filling of the uterus, the successive aspects of the injection, the advance of lipiodol into the tubes, and its entrance into the peritoneal cavity. These details were clearly visible by making use of the Potter-Bucky diaphragm and of a fixed or mobile grill.

Dr. Lobre then proceeded to illustrate on the screen the information which could be supplied by radiographic examination—anomalies of development, and variations in the form and dimensions of the uterine cavity and in the position of the uterus. Examination also showed alterations of the uterine mucosa, polyps, submucous fibromas, tumours, and other conditions which might require curettage, also the sensitiveness of the uterus and the irritability induced by application of severely caustic agents to the mucosa. Lesions of the tubes, *which might escape detection* by clinical examination, could be shown, notably those causing impermeability of the cornu or at the isthmial region. Variations of the length, calibre, and form of the tubes could also be observed. The contractions, which were clearly visible in normal tubes, did not occur in diseased tubes that were distended with lipiodol, which they retained for a very long time. In certain sterile women the tubes were firmly fixed by adhesions, remaining always immobile. There, said Dr. Lobre, were *the lesions, anatomical* and physical, revealed by hysterosalpingography. However highly the method might be perfected it would never constitute a specific treatment for sterility, since some forms were not mechanical in origin. The method confirmed and precisely demonstrated the clinical findings, and likewise supplied data giving rise to new medical and surgical methods of treatment.

For combating uterine or tubal spasm antispasmodic agents, such as belladonna, atropine, benzyl, or the bromides, might be used. Tubal atony might be treated with gynaecological massage or diathermy, which were equally useful in uterine displacements. If the tubes presented undue small calibre, they might first be rendered permeable by injecting them with lipiodol, and their dilatation might then be attempted by repeating insufflation for a sufficient number of times.

Before undertaking operative measures designed to combat sterility, hysterography should be practised. Ligamentopexy, or stomatoplasty, should not be attempted without being assured that the tubes were permeable. If permeability was not present an attempt should be made to restore it. Twenty operations of this kind had been undertaken by Dr. Lobre following advice based on radioscopic findings. Thus far the results had not been satisfactory, and in no case had pregnancy followed surgical treatment. Operation had generally proved to be too late, and had revealed old and already organized lesions. In the future operation must be done earlier, indications must be more clearly defined, and technique must continue to improve. Radiographic examination not only permitted etiological diagnosis, but often sufficed in itself to constitute the treatment of certain forms of sterility. Various statistical records had shown, like those of Dr. Lobre, that pregnancy might be obtained in about 10 per cent. of the cases examined. While this might seem a very modest result, it must be remembered that the method was resorted to when every other method had already failed. Again, the figure of 10 per cent. was a gross figure and included the cases in which the tubes were permanently obliterated. In many cases tubes originally considered impermeable proved capable of receiving injections, provided that the cervix was well drawn down and the pressure continued for a sufficient time. By following the principles described she and her colleagues had obtained 23 pregnancies following 230 injections with lipiodol. In three of these successful cases a second pregnancy had occurred, and in one case a third. There had been only one case of extrauterine pregnancy.

In the discussion that followed, the PRESIDENT pointed out that the method might not be very easy to apply in private practice, where facilities for re-examination after three or four hours might not always be obtainable. Lady BARRETT inquired how it could be ascertained with certainty that no infection of the tubes existed. Was Dr. Lobre confident that forcible injection into the tubes was safe? Dame LOUISE MCILROY said she expected to get more than 10 per cent. of successful results with douching and other methods, including insufflation. It was sometimes difficult to detect pus in the tubes, and if injections were made in the presence of a pyosalpinx trouble was to be expected. A closed tube had possibly been the subject of inflammation at some time. Miss MARTINDALE asked what results had been obtained by Dr. Lobre by means of artificial insemination.

In reply, Dr. LOBRE said that some gynaecologists sent patients to a radiologist, and allowed them to go straight home, but she preferred them to lie in bed for one or two days, and the examination, therefore, must take place either in a hospital or clinic. None of the patients had had a rise of temperature after the injection. She had had no successful cases after artificial insemination. The results after *lipiodol* were possibly better than they appeared to be, because hospital patients did not always report subsequent pregnancies.

Dr. JANE WALKER proposed, and Professor MELLANBY seconded, a vote of thanks to Dr. Lobre for coming to London to give this valuable address.

Ireland.

The Samaritan Hospital for Women, Belfast.

At the annual meeting of the Samaritan Hospital for Women, Belfast, on March 14th, Professor A. Fullerton, M.B., C.M.G., president of the Royal College of Surgeons, Ireland, advocated the institution of paying wards in their Belfast hospitals. The status of patients, he said, had completely changed in recent years. It was unfair to the public and to the medical profession that voluntary service should be given by honorary medical staffs to patients who were able to pay for their maintenance and treatment. The present system led to grave abuse of the hospitals on the one hand and the exploitation of the profession on the other. It seemed anomalous that the resources of their modern hospitals should be reserved for a single class, and that those who contributed to provide that class with free medical and surgical treatment should have to be satisfied with inferior equipment. Surplus funds derived from pay-wards were of great assistance to the finances of a hospital. The Duchess of Abercorn, who presided at the meeting, expressed her agreement. Dr. T. R. Mackenzie submitted the medical report, which recorded that 635 patients had been admitted during the year, and 699 had been treated in the out-patients' department. The surgical staff had at its disposal the largest single supply of radium in Ulster.

Free State Medical Registration Council.

It is understood that Mr. William Doolin, F.R.C.S.I., of Dublin, will be selected to represent the Irish medical profession to fill the vacancy created by the death of Dr. T. R. J. Hayes, F.R.C.S.I., on the Irish Free State Medical Registration Council. Mr. Doolin graduated M.B., B.Ch., B.A.O. at the National University in 1910; and became Fellow of the Royal College of Surgeons, Ireland, two years later. He is surgeon to St. Vincent's Hospital; a past-president of the Leinster Branch of the British Medical Association; a member of the Irish Medical Association; honorary secretary to the Dublin Local Medical Committee; and a member of the Irish Medical Committee. Mr. Doolin is a well-known writer on surgical and educational subjects, and is editor of the *Irish Journal of Medical Science*.

Local Authorities (Officers and Employees) Act, 1926.

The report of the Select Committee of the Dail on the Local Authorities (Officers and Employees) Act, 1926, has been circulated to members of the Dail and Senate. Of the 49 local authorities in the Free State invited to submit their views, 117 sent replies. Twenty-three local authorities out of the 249 in the Free State actually declared their opposition to the principles of the Act, which took out of the hands of the local authorities the right to make appointments. Memorandums were received from, among other bodies, the Irish Medical Committee on behalf of the members in the Free State of the British and Irish Medical Associations, and non-members of both medical bodies. The medical members of Dail Committee were Dr. T. Hennessy, T.D., Irish Medical Secretary, and Dr. C. Ward, T.D. The committee's first recommendation is that the functions assigned to the local Appointments Commissioners should be fulfilled in future by the Civil Service Commissioners, or, in other words, that the Local Appointments Commissioners should disappear. In the event of the foregoing recommendations not being accepted the committee recommends that only a person in the Civil Service shall be eligible for appointment as a Commissioner under the Act. Another recommendation proposes to take out of the hands of the local authority the only power it now possesses in respect of promotion within its service, and to place all such matters under the control of the Commission. It is recommended that regulations prescribing the qualifications for all offices comprised in any particular description, class, or grade of office to which the Act applies shall be laid before each House of the Oireachtas as soon as may be after such regulations have been made. Other recommendations are: that provision should be made for competitive examination by way of written tests for all appointments to the public service other than appointments requiring professional or technical qualifications. That for appointments requiring professional or technical qualifications, examinations should be held by the Local Appointments Commission acting by selection boards appointed for the purpose; that such boards in choosing candidates with a view to appointment should have regard to the post-graduate diplomas or similar distinctions, and the experience of the candidates, the latter qualifications to be ascertained by a practical test. That it should be a statutory instruction to the selection boards that in assessing the relative merits of candidates in regard to the factor of personality, marks should be awarded only in respect of personal appearance and general bearing, and that the maximum number of marks prescribed under that heading should not be greater than is represented by 5 per cent. of the total number of marks obtainable. That with a view to the filling of appointments requiring professional or technical qualifications, rosters of qualified candidates should be framed by the Local Appointments Commissioners as often as the number or expected vacancies justifies, but not oftener than four times a year, based on the procedure outlined as regards examination by selection boards; that each such roster should consist of such number of qualified candidates as is necessary to fill the estimated vacancies in the particular class of appointments occurring within the ensuing period; and that any candidate for inclusion in such roster should be entitled to be informed of his place in the order of merit as determined by the said Commissioners. That every selection board to be set up by the Commissioners for the selection of candidates with a view to any recommendation for appointment under the Act should be constituted with the assistance of the expert advice of the Department of State concerned. That if in any case the Commissioners do not recommend for appointment the candidate placed first in order of merit by the selection board the Commissioners shall inform the selection board as to the reasons for not recommending such candidate for appointment.

Scotland.

Mental Clinics in Scotland.

An address was delivered to the Edinburgh's Women Citizens' Association, on March 18th, by Dr. Hamilton C. Marr, senior commissioner of the Board of Control for Scotland. In considering the treatment of mental patients under the conditions that apply to those in general hospitals Dr. Marr stated that in 1932 tuberculosis was four times more prevalent in asylums than in other hospitals. The sanatorium for tuberculosis at Woodilee Asylum was the first to be established in any asylum. In applying the idea that mental disease was closely associated with physical disease the Glasgow District Board of Control established a reception house for the treatment of mental patients in Glasgow parish passing to the district asylum at Lenzie. In five years about 2,000 patients were treated in this relatively small hospital, which was under the care and supervision of women nurses. It was found unnecessary to hamper the freedom of the patients in any way. Mental observation wards were subsequently established in some of the large cities—for example, in the general Poor Law hospitals at Duke Street and at Stobhill in Glasgow. These experiments had indicated that it was desirable to allow patients who were mentally affected to be treated by ordinary hospital methods, and thus to dispense with the necessity for certification, which constituted legal insanity. It would be an ideal scheme to build four large clinics in the four university cities, with subsidiary small clinics and dispensaries scattered throughout the surrounding areas. A clinic in Paris has been treating nervous and mental affections of this kind for several years. Dr. Marr thought that such a scheme might be financed out of the Government Lunacy Grant for Scotland, which amounted to £115,000 per annum. This sum

was regarded at present as a subsidy to parish authorities, and was largely used not for the benefit of the insane, but for the relief of the rates.

Glasgow Cancer Hospital.

At the thirty-ninth annual meeting of the Glasgow Royal Cancer Hospital, on March 21st, Sir John M. MacLeod, Bt., president of the hospital, who occupied the chair, referred to the rapid development in the medical and surgical treatment of cancer both in Glasgow and elsewhere. Dr. Macfarlane said that the public attitude towards the cancer hospital had changed in recent years; there was a fair assurance that many patients would be greatly improved, if not completely cured. It was largely due to the foresight and wisdom of Sir George Beatson that the hospital had maintained its careful inquiry and investigation into all cases of malignant disease, and that efficient research workers were carrying on their experiments in a well-equipped laboratory. Radium was the best treatment available for inoperable malignant diseases. Dr. R. P. Peacock, director of research at the hospital, referred to its policy of supplying radium to other institutions. He thought that this had been justified by the work of the Radium Commission, which was now developing this policy on a vast scale throughout the country. Radium treatment, he said, was a growing science, and research must go hand in hand with clinical work. Treatment by radium had the advantage over surgical methods in that it exercised a more destructive action on cancer cells than on normal tissues. Research was aiming steadily at a form of treatment which could be called a cure. One of the great objects of research in the meantime was to determine the nature of the selective action which radium therapy had upon malignant tissues. According to the report for the year 479 patients were treated in the hospital, and 26 as out-patients. To assist in the efficient administration of the supply of radium, the Glasgow and West of Scotland Radium Institute has been formed. It occupies a building adjacent to the hospital, in which about twenty beds will shortly be available. A scheme has also been arranged by which radium will be lent to four city hospitals, so that [illegible] institutions in Glasgow will be combining their experience in using radium for the treatment of cancer.

Royal Victoria Hospital Tuberculosis Trust.

At the annual meeting of contributors to the Royal Victoria Hospital for Tuberculosis Trust, held in Edinburgh on March 19th, Sir Ralph Anstruther, president of the Trust, who presided, referred to the research in prevention and treatment that was being done at Southfield Sanatorium, where an early extension of the children's accommodation was contemplated by the Trust. Dr. Haig Ferguson, President of the Royal College of Surgeons, expressed the opinion that tuberculosis would be abolished altogether in the present century. Having commented on the fact that the Trust was beginning to get money for research, Sir Robert Philip said that tuberculosis was a universal disease, which arose from a very simple infection; its development, however, could be arrested. Very serious cases of tuberculosis were exceptional. The present campaign against the disease was successful, and would probably be more successful in another generation. The report for the year ended June 30th, 1929, deals with the activities of the Trust for the care and prevention of tuberculosis throughout Scotland, and with the work of the sanatorium colony at Southfield near Edinburgh. Attention is directed to the importance of observing the occurrence of tuberculosis in the nursery and in the school. The results obtained in the sanatorium have been very satisfactory. An increasing number of applications for the admission of children were received from widely separated areas in Scotland; 50 per cent. of the cases are nursery cases. The report points out that skilled treatment and a process of de-tuberculization may immunize the child in some degree against the further effects of infection; in this way the early infection may become a means of security against tuberculous disease in later life. Attention is drawn to the fact that the falling mortality rate of tuberculosis is one of the striking results of modern methods of treatment. A continued decrease in the mortality of some countries as compared with others is stated to afford a commentary on the effectiveness of concerted measures. Reference is made to the Gracemount farm in supplying certified milk; and to the establishment of a tubercle-free herd of 110 cows that are subjected to rigid six-monthly tuberculin tests. An investigation is being made to ascertain to what extent cattle are liable to human infection, and the channels by which such infection is transmitted. The committee of the Trust appeals for a sum of £600 per annum to be used for research during the next five years.

Edinburgh Royal Maternity Hospital.

At the annual meeting of the Edinburgh Royal Maternity and Simpson Memorial Hospital, held in the City Chambers on March 20th, Lord Provost Whitson, who presided, referred to the amalgamation that was about to take place between the hospital and the Royal Infirmary. The new maternity department of the Royal Infirmary, he said, would not be ready for five or six years. Meanwhile the Maternity Hospital required increased support to prevent encroaching on its reserves. According to the report for the year, 2,351 patients were treated in the hospital, which was a record for any single year since its foundation; there was an increase of 157 over the figure for the previous year. The total number of patients, including those admitted to the hospital and treated in their own homes by nurses from the hospital, was equivalent to 41.6 of the total number of births in greater Edinburgh during 1929. The report points out that the site for the new maternity department of the Royal Infirmary will be one of the best in the city, being in the grounds occupied at present by George Watson's School. The maternity clinic, which will have 120 beds, will retain the name of "The Simpson Memorial."

The Late Miss A. W. Gill.

The death took place at Hove, on March 2nd, of Miss Annie Warren Gill, who was lady superintendent of nurses in the Royal Infirmary, Edinburgh, for eighteen years. It was at this institution that she received her nursing training. In 1900 she served as matron of the Edinburgh South-East of Scotland Hospital in the South African war, and took a party of nurses the following year to South Africa for service in the concentration camps. In 1903 Miss Gill was appointed matron of the Royal Berkshire Hospital at Reading, and four years later became lady superintendent of the Royal Infirmary, Edinburgh, from which [illegible] she retired in 1925. [illegible] many improvements in the nursing department of the Royal Infirmary were made during her tenure of office. During the war she did much work in obtaining and supplying trained nurses for military and naval service, and in raising and organizing a large staff of junior V.A.D. nurses. She was awarded a bar to the Royal Red Cross, which had been presented to her for service in South Africa. She was president of the Scottish Matrons' Association from 1910 to 1925, and was elected president of the College of Nursing in 1927.

England and Wales.

Health and Cleanliness Council.

THE Health and Cleanliness Council, a body whose object is to spread information as to the advantages of cleanliness and other healthy practices by educational and propagandist means, held its fourth annual general meeting at the Hotel Cecil, London, on March 19th, under the chairmanship of Dr. G. F. Buchan. At a luncheon preceding the business meeting, which was attended by many medical officers of health and others, the guest of honour was Professor Louise McIlroy, director of the obstetrical and gynæcological unit, Royal Free Hospital. Whatever might be the truth, said Professor McIlroy, in the statement frequently made that it was impossible to make people clean by Act of Parliament, she was sure people could be made clean by that means. At the bottom of the whole of child welfare work in connexion with maternity and child welfare was the "push" for cleanliness. The slogan of the [illegible]

"Where there's dirt there's danger," was nowhere more apt than in this relation. Antiseptics and disinfectants were all very well, but the ultimate protection must be in the normal physiological state of the person, and one of the principal fortifying factors was cleanliness. Incidentally she begged the council to turn its attention to the fashion which was now ordaining the return of the long skirt, an unhygienic garment whereby the wearer swept up every species of germ and dirt as she went along. Dr. Buchan said that health and cleanliness were indissolubly associated. Sanitation was nothing more than common sense. He pointed out how many things in the evolution of human society began as aesthetic preferences and were presently shown to have health value. The Romans could not have known that the act of bathing would eliminate harmful germs, but they practised it assiduously. The best example of sanitary achievement in this country was the virtual stamping out of typhoid fever; the residuum was almost entirely due to the fact that certain persons with dirty or infected hands manipulated foodstuffs. He wanted to see in every place where food was prepared the slogan "Cleanliness first." As illustrating the value of washing facilities, he mentioned an area of which he had experience, inhabited by four or five thousand families, only one hundred of whom had bathrooms. Was it wonderful that the infectious disease rate in that area and also the proportion of unclean children who had to be dealt with at school were higher than in the case of surrounding areas? He pointed out the importance of cleanliness in connexion with maternity work. Four out of every 1,000 women died in the process of confinement, and two out of the four died of puerperal sepsis, which was really dirt. The report of the council showed a great deal of activity during the year in the way of distribution of literature, exhibition of films, delivery of lectures, and assistance in local health and baby weeks. The council has an encouraging list of members in the shape of local health and education authorities and voluntary associations.

Training School for Nurses: Opening by Prince George.

A new preliminary training school for nurses, presented to University College Hospital, London, by the Rockefeller Foundation, was opened by H.R.H. Prince George on March 19th. The ceremony took place in the medical school library. Sir Herbert Samuelson, chairman of the hospital, in an address of welcome, said that as long ago as 1862 the hospital enlisted the services of refined and educated women to take charge of patients. Attempts to consolidate the nursing service as a whole on a professional basis, however, appeared to be unsuccessful until the experiences of the war brought into being the College of Nursing. With the institution of the College and the General Nursing Council the training and teaching of nurses became standardized to an extent little contemplated by the earliest pioneers. The American ambassador (General Dawes), in seconding the address, spoke of the establishment of the nursing school as another evidence of mutual understanding between the great English-speaking peoples. The gift by the Rockefeller Foundation was a great tribute to the work carried on at University College Hospital, and also a tribute to the nursing profession, one of the noblest avocations of women. Prince George, in reply, referred to developments which had already been possible at University College Hospital through the generosity of the Rockefeller Foundation—a new maternity hospital, new nurses' homes, a new wing in the main hospital, new theatres and laboratories, and important extensions to the medical school. The latest and by no means the least important of these gifts was the new preliminary school for nurses. "I feel we must all acknowledge our debt to the skilled doctor and the trained nurse, and to the hospitals which educate them. Personally, I have a very special reason for paying a tribute to doctors and nurses, for I know that to skilful treatment and devoted nursing the King's recovery from his serious illness is very largely due." The Prince accepted from Miss Darbyshire a silver statuette of a nurse in her first nurse's uniform. The new training school building is one of six floors, and includes an oak panelled dining room, a practice kitchen, a laboratory department, and a demonstration room, the last-named being fitted like a ward. The carefully prepared curriculum includes such subjects as anatomy, physiology, practical nursing, hygiene, first aid, and cookery. Accommodation is provided for two sister tutors, a staff nurse, and twenty students, in addition to quarters for the domestic staff. The period of preliminary training is two months. During the second month the student will visit the hospital daily and engage in ward work, and at the end of the preliminary training, having passed an examination in the theory and practice of nursing, she will be accepted as a probationer in the hospital.

The Northcote Trust at St. Thomas's Hospital.

The report of the Cicely Northcote Trust at St. Thomas's Hospital for the year ending October, 1929, recalls the death this year of Mr. Hugh Stafford Northcote, who founded the trust twenty years ago in memory of his sister Cicely. This is also the first report issued under the almonership of Miss C. Morris, who has recently succeeded Miss Cummins on the latter's retirement from the post. Among the activities of the trust there is a club for the fathers and mothers of St. Thomas's maternity department, which provides classes on housewifery for mothers, addresses by doctors from the hospital, and debates for fathers, social evenings with music and dancing for both, and attendance by voluntary workers for children up to the age of 5. The assistance given to patients in the wards of the hospital varies from advice on how to maintain the home during illness to the provision of a bath chair or surgical boots to a cripple who aspired to become a girl guide, and the successful enlistment of a would-be suicide into a British regiment. The Northcote Trust almoners supervise the financial measures necessary in the distribution of insulin to diabetics when they leave the wards; they provide after-care for cancer patients; and they run a hostel for girls and women from the venereal disease clinic who cannot live at home or have no home to go to. The work of providing these girls with some philosophy of life is admitted to be difficult, but while there are failures there are also said to be many splendid successes. The almoners visited some 9,000 patients in the wards or in their own homes during the year under review; but notwithstanding contributions from the patients and a grant from the Ministry of Health, the admirable work of the trust is hampered by lack of funds. An appeal is made for further donations and subscriptions.

India.

Public Health in Bombay.

THE health history of the Presidency of Bombay shows steady progress to 1929, a record year for low mortality, then a steady decline to previously low standards. Cholera was subsident in 1928, the death rate being 0.36 as compared with 1.35 the previous year, when over 26,000 deaths were recorded. Plague, fevers, and respiratory diseases were more active. A slight decrease in malarial mortality was due to improvement in Sind. Grants for the free distribution of quinine were sanctioned by the Government. From an experiment conducted in selected schools regular quininization of the children is reported to have reduced enlargement of spleen. There was a keen demand for the drug both as a prophylactic and as a curative, but the policy of quininization was expected to be thoroughly revised in 1929 on account of an uncertainty of its potency against malaria. Influenza had the mildest effects since 1926, but deaths registered as due to fevers and respiratory diseases were often caused by the sequels to influenza. The marked variation in the prevalence of phthisis in different cities, and sometimes in different communities of the same city, showed that it is so related to social customs and modes of intercourse that special inquiry is desirable. The death rate for pneumonia in Karachi was the highest in ten years. Plague increased in spite of a larger number of revaccinations. Cobra bites accounted for 35 accidental deaths, the periods of expiration varying from thirty minutes to fifteen hours. An important part of medical

policy in 1928 was the extension of village sites. Healthy sites were selected and laid out in building plots for four villages, and land was acquired for the extension of others. Less satisfactory was the condition of industrial workers. Some factories inspected in the Gujarat district were found to be insanitary; no provision had been made for first aid; there were no crèches; light and ventilation were defective, and drinking water was objectionable. None of the factories inspected by the public health staff had any welfare scheme for its workpeople. Health and baby weeks, however, are reported to be more popular. Magic lanterns and cinemas are extensively employed for propaganda. A more novel form was a drama dialogue on maternity, written in the vernacular, and presented on the stage. In commenting on the improvement in the rate of maternal mortality Dr. Munsiff, Officiating Director of Public Health in Bombay, draws attention in his report to the excellent work that is being done in the maternity homes throughout the Presidency. With the exception of 1914 the birth rate for 1928 was the highest recorded, representing an increase of 25.362 on the previous year, but the increased death rate was more than proportionate. Over 130,000 infants died during the first year of their lives, and 36 per cent. before the end of the first month. More than three-fourths of the total infant mortality was due to respiratory diseases, infantile debility, and premature births. Poverty and ignorance accounted partly for these high rates; contributory causes are considered to be malaria, syphilis, and the practice of soothing infants with opium. The proportion of deaths to births varied inversely according to the number of rooms occupied by the parents. Preventive measures were continued with favourable results. There was a slight decrease in the number of unattended births, and in confinements managed by unskilled women. Over 40,000 visits were made by municipal district nurses. Necessaries and comforts were more generally accepted. The infant milk depots, which provided pure milk daily, have been closed, as their work was being done by the welfare centres.

Research at the Haffkine Institute.

As a result of renewed investigation in plague parasitology during 1928, on the lines recommended by the Plague Expert Committee of the League of Nations, successful transmission experiments were made at the Haffkine Institute with *Xenopsylla cheopis*, *X. astia*, and *X. brasiliensis*, the three species of flea found in Bombay. The last-named species, which forms a large proportion of the rat-flea population in the southern provinces, had not been proved before to be a carrier of plague in India. In each experiment thirty-six fleas—six males and six females of each of the species *Xenopsylla cheopis*, *X. astia*, and *X. brasiliensis*—were kept in a cage with a plague-infected rat. On the death of the animal the surviving fleas were collected, identified, and kept singly in labelled tubes. They were then fed individually for two or more successive days on healthy rats, and the process of feeding was observed under an entomological microscope. There were three successful transmissions. The fleas fed on the rats had been male *X. brasiliensis* in two cases, and female *X. cheopis* in the third. Another method of investigation was employed to demonstrate whether *X. astia* and *X. cheopis* were capable of carrying epizootic plague under optimum conditions. Two flea-proof pits were constructed and proved satisfactory. These experiments furnished results differing considerably from those previously accepted as correct.

The importance of [illegible] 1928 Major Sokhey, I.M.S., acting in the nursery and the Institute during the greater part the sanatorium has that anti-plague inoculation is being ing number of [illegible]ed as a protective measure in almost were received from [illegible]t two million doses of Haffkine's pro- 50 per cent. of the [illegible]buted throughout the continent and points out that six[illegible] months. Since the opening of the tuberculization may [illegible]e million doses have been sent out. against the further [illegible]ture remained the same, but a early infection may be[illegible] discovery that the blood agar tuberculous disease in la[illegible] for the growth of *B. pestis*, the fact that the falling [illegible] with greater certainty con- one of the striking results o[illegible] prepared vaccine. Thirteen A continued decrease in the[illegible]dicated that the agar-grown vaccines of the Farbenindustrie, Hoechst-am-Main, Germany, of the Pasteur Institute, Paris, and of the Lister Institute, London, conferred a lower degree of protection, even when employed in doses recommended for man, than 0.5 c.cm. of Haffkine's prophylactic. Researches in anaemia by Major Sokhey and his assistants revealed that anaemia of sprue and of pregnancy had great resemblance to pernicious anaemia; they believed that the so-called anaemia of pregnancy is not a distinct entity, but merely an aggravated condition of anaemia commonly present in non-pregnant women. All cases of macrocytic anaemia with high colour index were examined to ascertain in what respects sprue and severe anaemias of pregnancy differed from pernicious anaemia, and how the three conditions responded to liver treatment. In an investigation of the anaemia of pregnancy, associated with a special inquiry into maternal mortality during childbirth, serious difficulty in treatment was brought to light; women delayed too long in coming to the institute, and liver extract was too expensive for general use.

The Dufferin Hospital, Rangoon.

The annual report of the Dufferin Hospital, Rangoon, for 1928, which has been recently received, appears in a new form with a considerable increase in the amount of information. The superintendent, Major M. L. Treston, I.M.S., mentions that the gynaecological block of seventy-six beds had not been completed at the time of the report; the gynaecological work was therefore continuing in the Civil General Hospital, Rangoon, as in the past. The ground floor of the old Dufferin Hospital building has now become an out-patients' department, with ante-natal and infant clinics. A new main block for maternity cases was opened in November, 1927, and contains 100 beds; there is also now an isolation block with twenty-four beds.

Correspondence.

RESEARCH IN MEDICINE.

SIR,—As one engaged in clinical research, I welcome the article of Sir Thomas Lewis on clinical research and the difficulties under which it now labours (March 15th, p. 479) as well as your leading article and the statements of the Medical Research Council on the subject. For with the better recognition of the fruitfulness of this field of work will surely come the money necessary for its cultivation. The question is, as I see it, primarily a financial one; when the physician can see his way to gaining in this absorbing branch of medicine a permanent appointment and a salary not too incommensurate with the income he can gain in other fields, there will be no lack of good candidates capable of extending the bounds of scientific medicine.

Possibly many members of the profession do not realize the barriers in the way of clinical research at the present time as the result of the financial position. The Medical Research Council temporarily assists many workers, clinicians among them, with annual grants, but its permanent staff has up to now consisted almost entirely of laboratory workers. There are for research in medicine and the ancillary sciences a moderate number of short-period scholarships of £150 to £300 or perhaps £400 per annum, the larger ones being usually full-time. Those offering more than £400 per annum are rare. Some of the scholarships are available for clinical research, though in practice the great majority are awarded to laboratory workers. They usually go to men who have already a number of years of post-graduate work behind them, and who are, therefore, already men of considerable experience. They may have conditions attached which render it difficult for the holder to get or to keep a footing on the clinical side of any hospital. Without this footing he cannot get control of clinical material, and he is not likely to be able to carry out clinical research. But suppose he is lucky, and possesses a clinical appointment, such as honorary assistant physician, when his scholarship comes to an end he finds it is no stepping-stone to another post appointment. He may, of course, wait month after month

ntil another similar research grant or scholarship is warded him after elaborate application, but there is no ore security of tenure with the second one than with the rst. He knows he will be out of a job again within a w years, however good his work. Hence, after his first ppointment, he will probably be faced with the choice of ther clinical work in practice or research work in a boratory—clinical research is financially a blind alley -day. He may, of course, elect to do clinical research id to earn the whole or most of his livelihood by other rts of work. If so, he must face a constant frittering vay of energy and the unsettledness of divided aims.

The training of clinical research workers is discussed Sir Thomas Lewis. An association for these workers, ch as he suggests, seems a most attractive method of romoting their intellectual as well as other interests by utual contact and criticism. There is one point on which, owever, I feel I must have misunderstood Sir Thomas ewis's meaning. He seems to imply that a training in search renders a man less fitted for diagnosis and for the eatment of patients. If this were so, it would cut the ound from under our feet, for no hospital would appoint "research physician" in such circumstances; moreover, e profession would be the first to proclaim the absolute cessity of putting the patients' welfare first. Coming om such an authority, a suggestion of the sort would turally be extremely serious, and as other may have read e paper in the same sense I much hope Sir Thomas Lewis ll contradict this if it is not his opinion.

I understand he favours strict specialism in the research rker, whereas some individuals, at any rate, would find a definite advantage to maintain a more general contact th medical work and to continue to deal with patients d diseases of many types, instead of restricting themves wholly to the type of case under investigation. One vantage is that a balanced outlook is thus more easily aintained and too narrow views avoided—an advantage th to the patients and to the research; another, that allows the worker better facilities for the selection of ses for investigation instead of rendering him wholly pendent on others for sending him the type of case he quires.

The conflicting claims of the individual patient and of perimental medicine are, of course, obvious; no clinical periment can be pushed to its logical conclusion like a boratory experiment. But the training of the young search worker in his early post-graduate years with his lleagues who intend to undertake private practice should, d I believe would, inculcate in both the same solicitude r the patient which is customary in our profession. In s letter (March 22nd, p. 565) Dr. J. A. Ryle touches on e same question—namely, "How can curative and experiental medicine be divorced (or reconciled)?" I suggest at all of us in clinical medicine are experimenting, but at usually we have not the opportunity of so conducting d controlling our experiments and collating our data at we are able to deduce from them conclusions which ve been experimentally proved. When, for example, the lue of a given remedy is unproven, we are justified in thholding it in certain cases which will serve as controls: ien the value of a given remedy is proved the experimentalist is under the same obligation to his patients his fellow clinicians.

If clinical research is to blossom forth the financial rricades which at present close the road to all but the ry few must be removed and life-work in its service ade possible by the provision of adequately paid posts th security of tenure.—I am, etc.,

ondon, W.C.1, March 24th. H. M. M. MACKAY.

PPLICATION OF GAMMA RADIATION TO DEEP-SEATED TUMOURS.

SIR,—I was much interested to read Professor Joly's ter (March 8th, p. 466) suggesting a travelling bomb the external application of gamma radiation. A achine such as he describes was constructed for me some nths ago. It involves a very pretty mechanical movement, and if Professor Joly would care to see it I shall be very happy to demonstrate it to him at the London Hospital. It was considered by the Radium Commission last January, when the London Hospital applied for the four-gram bomb which has now gone to Westminster, and this was the method of mounting which I had suggested we might adopt.

On physical grounds I am very doubtful whether there is any future for the use of a bomb in radium treatment, but if it were to be of any use there can be no doubt that a travelling bomb would present great advantages in its application.—I am, etc.,

London, W.1, March 23rd. H. S. SOUTTAR.

INDIAN MEDICAL DEGREES.

SIR,—I entered the Indian Medical Service twenty-one years ago, and, having been closely associated with questions of medical policy at the headquarters of the Government of India, I have had good opportunities to observe the rapid growth in numbers and influence of the independent medical profession in India—the offspring, indeed, of the I.M.S. From this standpoint I deeply regret the action of the British General Medical Council in withdrawing recognition of the degrees of the various Indian universities for the purposes of registration. The decision is most inopportune, for it deals what may be a fatal blow at the delicate negotiations between the Government of India, the provincial Governments, and the universities and medical bodies for establishing a statutory All-India Medical Council, the duties of which would include the conduct of any necessary discussions with the British General Medical Council. The latter authority had expressed a desire to be in a position to treat with such a council, and negotiations in India have reached a promising stage. The action now taken in London has enormously increased the difficulty of settling satisfactorily for both countries the question of recognizable medical standards in India. Still worse, it will go far to alienate the good will and loyal co-operation of a rapidly increasing host of Indian medical practitioners, many of them trained in this country. Is it wise to discourage young Indians coming here to complete their medical education, and to encourage the setting up of barriers in a great profession which should be united, irrespective of race or creed, in its ministry for the good of mankind? Nowhere is the need for co-operation on a catholic basis more pronounced than in India. The work is and must be overwhelmingly in Indian hands; and it is satisfactory that the influence for good of the independent profession, trained in Western methods, grows year by year. It is impossible to overestimate the share its members are taking in the reform of obsolete religious and social customs which offer a great barrier to the spread of hygiene and health laws among the people. Details regarding this health and welfare work were given in my address last year to the East India Association (see *Asiatic Review*, July, 1929), and reports of progress continue to reach me.

No doubt the patience of the General Medical Council has been tried by discussions extending over ten years; but the effort should not have been abandoned when prospects of a settlement were a possibility. To close summarily further discussion on a question which not only concerns the Indian medical profession, but also the welfare of 320 millions of our fellow subjects, is, I venture with all respect to submit, a short-sighted negation of the breadth of view and statesmanship which should be exhibited by a body discharging the important statutory responsibilities of the General Medical Council. Unhappily, the issue is altogether wider than that of continuing to place a few Indian names on the British *Register* as eligible to practise in this country. The decision has added fuel to the smouldering fire of race conflict and antagonism which is so liable to break out in India under the stress of nationalistic susceptibilities. By taking a step which means the fanning of these embers the General Medical Council has rendered a great disservice to our fellow-countrymen in India, and not least to those of my own profession, whose task at the present time is none too easy.—I am, etc.,

T. CAREY EVANS,
London, W.1, March 24th. Late Indian Medical Service.

INJECTION TREATMENT OF VARICOSE VEINS.

SIR,—With regard to the article by Mr. Colt (November 9th, 1929, p. 848) and Mr. Hector's letter (December 14th, 1929, p. 1134), I should like to warn them both to verify how much of the pain is actually due to the salicylate. I have given many thousands of these injections, and I have often found the patient so worked up and nervous at the beginning of treatment that, in order to ensure that there shall be no reaction after the first injection, and that the patient will return, I inject only a minute dose, or even nothing at all. I have found several times, on questioning them, that they feel a typical "salicylate cramp," when the vein has been only pricked; it travels far up or down the leg, and, in my opinion, corresponds to the introduction of even a trace of the solution into the walls of the vein. On the other hand, many veins become sclerosed, without a trace of cramp. As regards the fear of blistering and ulceration: for the last five years I have used mostly a 20 per cent. salicylate solution, and find the risk absolutely negligible. The left index finger acquires wonderful skill in locating veins, and if all the solution is inside the vein there will be no ulceration.—I am, etc.,

Melbourne, January 21st. L. P. U. CRIVELLI.

STRUCTURE OF THE ERYTHROCYTE.

SIR,—In his paper on the structure of the human erythrocyte (*Journal*, March 8th, p. 433) Dr. W. E. Cooke claims to have demonstrated the presence of a spongy stroma. It seems to me that he has made the mistake of taking the appearances seen after the use of fixing reagents to indicate the real living structure.

In a paper on the nature of the red blood corpuscle (*Biochemical Journal*, 1924, No. 1, p. 202) I adduced a good deal of evidence that the corpuscle is a fluid droplet. Much of the evidence was already in existence, but I was able to furnish an additional and conclusive proof; it is briefly the following. When the corpuscles are freed from serum and suspended in a normal solution of sodium chloride they assume a spherical shape; and when they are again placed in serum they resume their original discoid form. It is inconceivable that these changes of shape should occur if there were a solid stroma.

I believe that the normal erythrocyte has no structure coarser than the micellae of the colloidal system which constitutes it, and these are, of course, ultra-microscopic.—I am, etc.,

Leeds, March 19th. ALFRED GOUGH, F.R.C.S.

ANAESTHESIA FOR SHORT OPERATIONS.

SIR,—Dr. Fisher Waddy (*Journal*, March 15th, p. 518), quoting Levy's work on adrenaline secretion under light chloroform anaesthesia, is following conclusions which, admirable in the laboratory, are daily disproved by the practical experience of anaesthetists in different places using this form of anaesthesia for minor surgical or obstetrical procedures with perfect safety. Moreover, before explaining any death under light chloroform anaesthesia or analgesia by Levy's adrenaline theory (in the dental case quoted from the lay press no evidence is produced to show that the anaesthesia was "light"), I suggest to Mr. Waddy that he ascertains: (1) the posture of the patient; (2) the preliminary preparation of the patient. (Chloroform associated with a stomach containing a fairly recent meal is not sufficiently regarded as a dangerous combination for "just a whiff"); (3) in dental cases, the absolute lack of obstruction to the airway. (Under chloroform anaesthesia anoxaemia can occur insidiously and dangerously when there is only *slight* obstruction); (4) the preliminary medication of the patient—whether atropine was given or not. It is my opinion that most fatalities under light chloroform anaesthesia can be ultimately ascribed to a fault in one of the first three causes.—I am, etc.,

H. K. ASHWORTH, M.B., Ch.B.,
March 17th. Visiting Anaesthetist, Manchester Royal Infirmary and Dental Hospital.

SIR,—My suggestion (February 22nd, p. 362) that chloroform should be used for such operations as tooth extraction, opening abscesses, etc., has met with considerable adverse criticism, owing partly, perhaps, to a misapprehension. I especially refer to the use of chloroform as an analgesic after inhalation lasting from forty to sixty seconds. My critics refer to the well-known danger of chloroform as an anaesthetic given to the degree of complete loss of consciousness, and this danger would certainly be accentuated by its administration in a semi-upright position. Undoubtedly most of the fatalities from chloroform are due to its narcotic effect on the respiratory and vasomotor centres in the medulla; the upright position, by the effect of gravity on the circulation through the medulla, would increase the danger, and lowering the head or inverting the patient is the most efficacious and rapid form of treatment. In fact, most fatalities are due to an overdose. When chloroform is given in the manner I suggest, as an analgesic, there is no loss of consciousness, no change of colour, no post-anaesthetic vomiting. The patient is able to understand everything that is said and to respond. He is conscious of the extraction of the teeth, but feels no pain.

Although, of course, the analgesic property of chloroform is made use of by nearly every practitioner in his practice of midwifery, I have not heard of any danger accompanying its use as an analgesic in this branch of medicine.—I am, etc.,

Ipswich, March 22nd. HERBERT H. BROWN.

THE RELATION BETWEEN GLANDULAR AND PULMONARY TUBERCULOSIS.

SIR,—In the March number of the *Edinburgh Medical Journal* there is an interesting article by Dr. D. McIver Dunlop, entitled, "The relation between glandular and pulmonary tuberculosis." Dr. Dunlop admits that his percentages are based on a smaller number of cases, but, even so, they are striking, because they do not agree with the commonly accepted figures. He states: "Out of the last 68 cases of pulmonary tuberculosis which have been treated in Southfield Sanatorium Colony 13 have been associated with a history of gross glandular disease, giving a percentage of 18.9." In all cases tubercle bacilli were present in the sputum, and the glandular involvement is unquestionable, only definite scars or gross visible swellings being accepted.

In Newcastle-upon-Tyne, at the end of 1929, there were 626 cases of pulmonary tuberculosis on the dispensary register with tubercle bacilli in the sputum; of these 21, or 3.3 per cent., gave definite evidence of cervical gland involvement. Going back to the period 1913-28, there were 1,227 notifications of involvement of the cervical glands, and of these 70, or 5.7 per cent., developed a lung lesion. In view of the great difference between the figures of the Newcastle cases and those quoted by Dr. Dunlop, I suggest that comparable statistics by other tuberculosis officers would prove very interesting.—I am, etc.,

GEORGE HUBBELL,
Newcastle-upon-Tyne, March 20th. Tuberculosis Medical Officer.

POSITIVE PRESSURE WITHIN PULMONARY CAVITIES.

SIR,—I was much interested in Dr. Vere Pearson's article on the pathogenesis of pulmonary cavities in your issue of March 1st (p. 380).

Coughing would, I think, only produce a positive pressure in a cavity if the following condition is fulfilled: during the expiratory phase of the cough the pressure in the cavity itself must not rise as much as the pressure in the bronchial tree generally; otherwise air cannot be forced into the cavity—it would rather tend to flow out of it. It would therefore be necessary for the cavity to be protected from the general intrathoracic pressure. A wall of fibrous tissue or consolidated lung might perhaps provide a sufficiently effective barrier for this purpose. I do not think that the mechanism described by Dr. Pearson would produce a positive pressure in a thin-walled cavity surrounded by more or less healthy lung tissue. There is, however, another way in which a decidedly positive pressure might be generated in a cavity. During a deep inspiration the

abnormally large volume of air might be sucked into the cavity. If the valvular opening postulated by Dr. Pearson were present this air could not escape, and on resuming normal respiration the pressure in the cavity would be positive both on expiration and on inspiration. In the case described by Dr. Pearson a pressure of 0 and +9 was apparently produced on normal respiration only (since he could not reduce the pressure below this level). If the patient had taken a deep inspiration I think it probable that the pressures on ordinary respiration would have subsequently approximated to the original figures of +4 and +16.—I am, etc.,

Davos-Platz, Switzerland, March 10th. R. L. OSMASTON.

DELINQUENCY IN BACKWARD CHILDREN.

SIR,—The interesting contribution which you published on the above subject (March 15th, p. 490) rather suggests, in its deductions, that actual feeble-mindedness does not contribute a large number to the class of moral defaulters. It appears that delinquents are apt to have an intelligence quotient of 60 to 70 per cent. This I find to be a fairly correct estimate in our Devon cases. There are exceptions at either end of the scale, and these, paradoxically, owe their condition to something of the same cause—namely, loss of interest in their field of enforced attention. The backward child is unable to keep pace with the subject of the lesson, and his mind turns to the easier paths of mischief; conversely, the very quick-witted child outruns the lesson, and requires mental diversion of a more adventurous and intriguing nature. Again, mischief is at hand to give him occupation, and irregularities in social adaptation, rather than a feeble intellect, lead him to delinquency.

I rather think, however, that we must not look only to backwardness and mental defect for the causes of this trouble (that is, delinquency), and we must not omit the strain of puberty (a very important cause, I think), the after-effects of encephalitis lethargica, epilepsy, and hysteria as contributing largely to this troublesome condition. My opinion is that delinquency is not actually *related* to either mental defect or backwardness, though often *associated* with it. If so, we must go further afield than inquiring how many backward children are delinquent, or how many delinquent children are backward. Delinquency appears to me to be a separate "county" whose borders often trespass upon the neighbouring ones of backwardness and mental defect.—I am, etc.,

Exeter, March 20th. CLAUDE A. P. TRUMAN.

ANAESTHETICS IN MIDWIFERY.

SIR,—In a letter in the *Journal* of March 15th (p. 517) Dr. A. M. Claye states, "Undoubtedly the question of expense *is* of the first importance." May I describe a method which, after the initial expense of £7 7s., costs from a fraction of a farthing to threepence, depending on the length of anaesthesia required?

Fit up a "Vernon Harcourt inhaler" and hang it on the bed-rail. Set the indicator at about two notches on the air side for the early part of the second stage and show the patient how to hold the face-piece, explaining that the apparatus only acts when the clicking of the valves can be heard. Tell her to apply the face-piece closely when she knows a pain is coming, and as the pain gets severe to hold her breath, etc., and only "breathe in" when she must, removing the face-piece when the pain has gone. The effect of this is mostly moral support. (The exhaust valve in the face-piece acts by gravity, and will require a small piece of cotton-wool in the valve case to keep it seated when the patient is lying on one side; this no doubt would be remedied by the makers if asked to do so.) Then, as the perineum bulges, ask the patient to keep the face-piece applied continuously. If she is still able to sleep between pains, increase the strength of the vapour during the pain. From now on the richness of the vapour will depend on progress. I aim at gradually increasing the amount of chloroform vapour as the pain gets more intense until the patient is unable to move while the head is being born, and yet is sufficiently conscious to obey instructions. One must remember that, whatever the patient may say or do, she is not responsible, and that a hysterical woman may struggle unless sufficiently deep. Immediately the baby is born the patient falls asleep and wakes, as the placenta is being expressed, with no memory of the actual birth.

The Vernon Harcourt inhaler is an apparatus which gives a *uniform strength of chloroform vapour in air*, easily regulated from pure air to a safe maximum percentage of chloroform vapour. It is a suction apparatus, and only acts when the face-piece is closely applied to the face. For these reasons it lends itself admirably to the self-administration of anaesthetics during normal and difficult labours not requiring instrumental treatment. The patient applies the face-piece closely until she becomes drowsy, when she automatically relaxes the pressure and stops the anaesthetic. Pain wakes her, and she repeats the manœuvre, thus rocking between partial consciousness and artificial sleep. Moreover, as the maximum percentage of chloroform vapour in the air delivered is not dangerous, the nurse can be safely trusted to give a short, deep anaesthetic if required.—I am, etc.,

Waltham Abbey, March 17th. R. H. CARTER, M.R.C.S.

DERMATITIS ARTEFACTA.

SIR.—Dr. Gardiner's case, reported in the *Journal* of February 15th (p. 282), brings back to my mind a similar experience of my own in 1912.

A cook was admitted to a country cottage hospital with a bullous eruption down the right side of her neck. This I decided must be a case of dermatitis herpetiformis. After a stay of three weeks all lesions were healed and the patient returned home. In the summer of 1913 she was readmitted with the same trouble. After a while I decided I would like further advice, and persuaded her to go and see Dr. Sequeira at his out-patients' clinic at the London Hospital. Dr. Sequeira wrote me that the condition was unquestionably artefact, and added that he was unaware of any other dermatosis giving lesions which formed a right angle! He suggested mustard as a possible agent. On her return the patient had more of the usual bullae on the neck. A search was made, and a small packet of mustard powder was found.

The amusing thing in this case was that when the patient went up to London she varied the procedure by buying a mustard plaster and putting this on her right upper arm before going to see Dr. Sequeira. Rather an insult, I felt, to his great knowledge and experience! This patient did not become toward; she tried to brazen it out, and wept tears of rage and mortification when she had to admit it finally. I discharged her, and received a letter from the secretary of the charitable society (who had sent her and paid for her) complaining of my harsh treatment. The success of her former imposture, coupled with the monetary benefits under the National Health Insurance Act of 1913, were the motives for her second visit.—I am, etc.,

Parkstone, Dorset, March 11th. J. CHARSLEY MACKWOOD.

The Services.

AUXILIARY R.A.M.C. FUNDS.

THE annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 2.30 p.m. on Friday, April 11th, at 11, Chandos Street, W.1, when the annual report and financial statement for the year ended December 31st, 1929, will be presented and the officers and committee for the current year elected.

DEATHS IN THE SERVICES.

Colonel Henry Kellock McKay, C.B., C.I.E., Bengal Medical Service (ret.), died at Hythe on March 14th, aged 79. He was born at Quebec on December 4th, 1850, the son of the late Major-General J. McKay, was educated at Guy's, and took the M.R.C.S. and L.S.A. in 1873; also the F.R.C.S. and the S.S.C. of Cambridge in 1876. Entering the I.M.S. as surgeon on September 3rd, 1873, he attained the rank of colonel on December 3rd, 1904, and retired on December 3rd, 1909. He served in the Naga Hills campaign on the North-East frontier of India, in 1875, and was mentioned in dispatches in G.G.O. No. 574 of 1875; in the Afghan war of 1878-80 (medal); and in the Mahsud Waziri campaign on the North-West frontier in 1881. He received the C.I.E. in 1899, the C.B. in 1904, and a Good Service Pension in 1909. He married Annie Emma, daughter of Mr. John Ringrose, of the Grange, Cottingham, Hull. She died in 1927, leaving one son.

Medico-Legal.

ALLEGED NEGLIGENCE AT OPERATION.
CROTCH v. MILES.

VERDICT FOR THE DEFENDANT.

An action for damages for injury alleged to have been received during operation was brought by Miss Martha Harriet Gordon Crotch of Vence, near Nice, against Mr. W. Ernest Miles, surgeon, of Park Crescent, N.W., and occupied the Lord Chief Justice and a special jury on March 13th and four following days.

Mr. J. W. Morris and Mr. W. A. Davies, instructed by Messrs. Churchill, Clapham and Co., appeared for the plaintiff, and Mr. Rayner Goddard, K.C., and Mr. H. C. Dickens, instructed by Messrs. Hempsons, on behalf of the Medical Defence Union, for the defendant.

Case for the Plaintiff.

Mr. Morris, in opening, said that the allegation of the plaintiff was that, after an operation on November 27th, 1920, for the removal of a fibroid tumour, Mr. Miles left in her abdomen a pair of forceps, 5 inches long, which was not discovered until an *x*-ray examination revealed its presence eight years later. After the operation in 1920 the plaintiff's life was one of continuous ill health, with a tragic succession of serious illnesses. Soon after operation a swelling appeared near the incision, and in May, 1921, she saw the defendant, who told her not to worry, as the swelling was the result of an injury to the muscles of the abdomen consequent upon the operation. In 1922 she went to India on family business, and was there ill and went into hospital. In 1925 she went to France to engage in a perfumery business, but was again ill, and had to give it up, and in February, 1926, in the South of France, where she had taken an antique shop, she was so ill that she was sent to a clinic at Nice, where an operation was performed for the removal of gall-stones. In August, 1928, still suffering, she consulted a doctor in Nice, and an *x*-ray photograph was taken, revealing the presence of the forceps, which necessitated a third operation. Since then she had suffered no pain.

Miss Crotch, in evidence, said that soon after the operation of 1920 she felt sharp pain in the abdomen. No organ of her body seemed to function properly. Pains of a distressing character made her life a misery. Medical men in India and France examined her without success. In 1922 she had a metallic taste in her mouth as if she were sucking rusty nails. She claimed special damages, amounting to £1,370, including payment for her gall-bladder operation, because she maintained she would not have had gall-stones if she had not been a sick woman by reason of the forceps.

Dr. R. H. E. Stevens testified to having been consulted by the patient on several occasions in 1921-23. She complained of a pain low down in the abdomen and swelling in the middle line, and attacks of nausea and sickness. He attributed it to ventral hernia following the operation.

The evidence of certain medical men, taken on commission in France, was read. Dr. Louis Prat of Nice testified that he operated on the plaintiff in June, 1926, at the Belvedere Clinic, and removed the gall-bladder, which was much diseased. He dealt only with the local condition, and did not explore the abdomen. He noticed a sort of rupture with a swelling or hard mass where the previous operation had been performed. The forceps, as shown in the *x*-ray photograph, was not in the region of his operation, nor did he use forceps of the type which was found. He admitted that nobody counted the instruments or swabs at his operations. His forceps were hinged, not screwed, as were the buried forceps. Dr. D. Maestracci of Vence stated that he examined the plaintiff in September, 1928, when she complained of severe abdominal pains and a persistent metallic taste. He was present when the operation for the removal of the forceps was performed. The forceps, which was removed from the small intestine, was rusty, and had lost all trace of nickel plating. Dr. Henry Fay of Nice, who performed the operation, said that the small intestine had to be cut to remove the forceps, which was coated with matter.

Case for Defendant.

Mr. Goddard raised the legal point that the action was barred by the Statute of Limitations because it was instituted more than six years after the alleged negligence, to which Mr. Morris replied that the plaintiff had displayed no lack of diligence in bringing her action, that the defendant had committed trespass upon the body of the plaintiff by leaving his forceps inside after operation, and that the trespass continued until the forceps was removed. The legal point was postponed until the evidence was completed, it being intimated that the defendant was desirous of giving his explanation.

Mr. Goddard said that one of the vital witnesses for the defence, the theatre sister present at the operation, was dead. It was on her that, in the patient's own interests, the surgeon should rely for the counting of instruments rather than delay the operation.

Mr. Ernest Miles, in evidence, said that although he had performed hundreds of operations since, he still had a slight recollection of this one, because the anaesthetist advised him to complete it as quickly as possible on account of the collapsed state of the patient. He always took the same number of instruments with him for every abdominal operation, unless special instruments were required, and to simplify counting he had them in threes and multiples of three. At the theatre he always counted his instruments out to the sister, and after operation the sister counted the instruments and swabs. If one was short a search would be made; sometimes one was found hidden in a towel. For the surgeon to hunt round for missing instruments or swabs would be to expose the patient to risk by delaying the operation. He had never lost a pair of forceps in the whole of his career. He produced the pair forceps which he was using at the time of this operation. On every pair were the letters "H.S.I." (Holborn Surgical Instrument Company). The forceps found in the plaintiff's body bore only the letter "H," which appeared where the "S" was on each of his instruments. He had never used forceps of the type found in the plaintiff's body for an operation of this kind.

In cross-examination, Mr. Miles stated that he took out a number of Spencer Wells forceps when he went to France at the beginning of the war, and some of them were exchanged for others which he received when the hospital was disbanded. He agreed that the removed forceps were of the type he had used some years ago, before he substituted stainless steel for nickel-plating, but he could not identify this instrument as one of his own. Asked by the Lord Chief Justice whether, if the buried forceps had been used for removing the gall-bladder it could have travelled down to the position in which it was found, he said that he thought so. In his view, judging from the *x*-ray photograph, the instrument was not found in the small intestine; it was in between the coils.

Dr. H. R. Wadd, medical superintendent of the nursing home where the operation was performed, said that he acted as Mr. Miles's assistant on that occasion. The theatre sister was very competent. He added that he had himself seen any number of Spencer Wells forceps for sale in France, and had himself bought some in Bordeaux and Paris four years ago.

Sir Hugh Rigby testified to Mr. Miles's reputation as a careful and skilful surgeon, one of the few who themselves counted their instruments after an operation. Usually a trained nurse attended to this duty.

Sir Thomas Horder said that he had known Mr. Miles for twenty-five years; his methods were those of a careful surgeon. Asked whose duty it was to check the instruments and swabs, Sir Thomas Horder replied that it was the theatre sister's, but he regarded the surgeon as ultimately responsible. Asked what would be his opinion of a surgeon in some country who said that nobody counted the forceps or the swabs, he said that he would not engage such a surgeon to operate on one of his patients. He also said that if forceps was left in the abdomen of a patient he would not expect an external lump to appear unless an abscess formed after a considerable time, and he could not think that a lump the size of a coco-nut, which the plaintiff said appeared in her abdomen in the neighbourhood of the scar two or three months after the operation, could have been caused by the presence of forceps.

Nurse Kingman, who was present at the operation in 1920, testified to the carefulness of the late Sister Brown, who regarded it as a "sacred duty" always to count the instruments. Mr. H. E. G. Boyle, anaesthetist, said that he had learned many years ago from Mr. Miles of his plan of having his instruments in multiples of three, which he thought excellent. Dr. J. S. Burn, who administered the anaesthetic for Mr. Miles, said that he had never known Mr. Miles fail to count his instruments after an operation. He added that he

had seen English-made instruments, surplus army stores, sold in France after the war.

Mr. Goddard, in his speech for Mr. Miles, said that Mr. Miles had evolved a system as near perfection as anything could be to get rid of the human element. During the actual operation it was reasonable and proper that the counting should be done by the sister-in-charge, but that did not free the surgeon from seeing that his instruments were right after the operation. He asked the jury to contrast the care which Mr. Miles had shown with the admitted practice of French surgeons in not counting their instruments.

The Lord Chief Justice: Dr. Prat went further than that: he said, "Nobody counts."

Mr. Morris, in his address to the jury, said that his learned friend had almost appealed to the jury not to find a verdict against someone who was a member of the medical profession. He would have thought, on the contrary, that once one was satisfied that it was at Mr. Miles's operation that the forceps was left it was in the interests of the medical profession itself that there should be a verdict against Mr. Miles.

The Lord Chief Justice's Summing-up.

The Lord Chief Justice, in summing up, addressed the jury for three and a half hours. He begged the jury not to be misled by the appeal for sympathy on behalf of the plaintiff. The task before the jury was a scientific one, and there the play of emotion was not helpful. With regard to the relevance of the evidence as to French practice, Lord Hewart said:

Let us put the matter the other way round. Suppose that the evidence about the operation conducted by Dr. Prat in France was that for years he had been conducting operations with the assistance of a careful method deliberately designed by himself to prevent an error about the number of instruments or swabs; suppose that Dr. Prat had been able to say, "I have designed a system of multiples of three. I count myself, the theatre sister counts, I check the counting of the theatre sister"; suppose that had been the evidence about Dr. Prat's operation, and when it came to Mr. Miles's turn he had to say, "I never count at all, and nobody counts for me; it is not done," how indescribably stronger the case against the defendant would have been. Now the position is reversed. The evidence of care in counting and of method in counting is the evidence of the defendant and the evidence given on his behalf, and it is conceded that in French operations there is no counting by the surgeon or by another. You may think it right to say that the measure of the additional strength that would have been given to the case against Mr. Miles if the position had been reversed is the measure of the assistance which his case derives from the knowledge which you now have that in the French operation there is no counting.

Lord Hewart then drew attention to the important dates in the case. From some accounts of the case one might think there had been only one operation; in fact, there were two, apart from the third operation to remove the forceps after it had been discovered. The first operation was by the defendant in November, 1920, the second by Dr. Prat in June, 1926, for the removal of the gall-bladder, and the third, for the removal of the forceps, by Dr. Fay, in September, 1928. He would put to the jury three questions:

1. Is it established that the forceps was left in the plaintiff's body in the course of the operation performed by the defendant?
2. If so, was that fact due to negligence on the part of the defendant or for which he was responsible?
3. The question of damages, if it arises.

As to damages, in addition to medical fees and expenses incurred, there was a claim for £500 in consequence of the plaintiff having to leave her Paris business on account of ill health, and a further loss on account of her business at Venice; but this related to the period antecedent to, and following on, the operation for gall-stones. The jury, if the question of damages arose, would have to decide whether these losses were attributable to what was done, or omitted, at the operation in 1920. Nobody denied for a moment that if a forceps was left in the body in the course of a surgical operation the patient ought to have a remedy in damages against somebody. But the question was whether the liability of this defendant was made out. It was for the jury to say whether it was established beyond reasonable doubt that this surgical instrument was left in the plaintiff's body in 1920 in circumstances which involved the operating surgeon in personal liability.

Lord Hewart proceeded to read passages from the evidence, especially by Mr. Miles, relating to the responsibility of the theatre sister in regard to the counting of instruments, and by Sir Hugh Rigby.

He (Sir Hugh Rigby) stated that in attendance at the operation are the surgeon, the assistant, the theatre sister, generally two nurses, and the anaesthetist, that the theatre sister is responsible for the instruments and their sterilization, the towels, and the swabs, and that she is very highly trained for this work. Sir Hugh Rigby said: "In our country she is something quite apart. She is specially trained for this duty, and has responsibilities which sisters in other countries are not given because they are not trained. I do not think one person can be responsible for all the details of the operation. The duty of counting instruments or swabs falls, according to the usual practice in this country, upon the theatre sister." Then came this passage, of no little importance in this case: "If the sister finds that she has not the right number she tells me. If I hear nothing I take it that all is correct. It is very seldom that I myself inquire. If I were working in a strange place or did not like the look of the sister"—he explained what he meant by that, that if he did not feel confidence in her—"I might do so." . . . He (Sir Hugh Rigby) went on to say that the standard of care in this matter of enumeration which was set and observed by the defendant was a standard higher than the ordinary, and a standard to which the ordinary surgeon could not be expected to attain."

The jury might think it right to draw a distinction between what was done in the course of an operation and what was done immediately at its close. It might well be that in the actual course of the operation it was not to be expected nor desired that the surgeon should be busying his mind with the counting of instruments or swabs, but that other considerations applied at the close of the operation, and that before the surgeon departed it was reasonable that he should personally satisfy himself that the number was correct, and that there was nothing missing. Mr. Miles said that he did that. Sir Hugh Rigby said that it was not usual, and he himself did not do it. These were material points with regard to the second question he had put to the jury, but that question did not arise unless the jury was satisfied that the forceps was left in the body of the patient in 1920. This was not quite a simple question. He quoted the words of Lord Chief Justice Tindal a hundred years ago, but unimpaired in their effect: "A person entering a learned profession undertakes to bring to the exercise of it a fair, reasonable, and competent degree of skill." Skill must be accompanied by diligence. Was it part of the duty of the surgeon personally to count the instruments and satisfy himself that the number was correct, or was he entitled to say that a skilled theatre sister was present, and that this was her job? She was not his servant; she was one of a team.

Turning to the main question, after reminding the jury that the burden of proof was on the plaintiff, and that it was not for the defendant to prove a negative, Lord Hewart said that, reviewing the evidence, two things leapt to the eye. The first was one to which he had already referred, that while all this detailed evidence was given as to the care habitually taken by Mr. Miles in checking his instruments, no such care was taken on the other side of the Channel. Everybody knew that some French surgeons were men of the highest degree of skill and enterprise. But in France it was not only that the surgeon himself did not perform this duty; nobody performed it. This type of accident was very rare. In more than thirty years' experience of the law he himself had never known a case of the kind. But if there was no counting by the surgeon, or by anybody on his behalf, was it difficult to understand that such a thing might conceivably happen? Lord Hewart explained to the jury the function of the forceps at operation, how it held the bleeding points until the ligature was applied. A row of forceps might be employed for an appreciable time, and when removed, if there was no counting, and especially if the patient was rather stout, the loss of a pair was a thing which might possibly happen.

The second thing which leapt to the eye was the remarkable contrast in the plaintiff's evidence as between the amount of medical testimony relating to 1926 and afterwards and the paucity of such evidence during the period from 1920 to 1926. Lord Hewart recapitulated the plaintiff's story. During the five and a half years between Mr. Miles's operation and that performed by Dr. Prat, when, according to this story, she was going about with this forceps in the lower part of her abdomen, what did she do? In July, 1922, she went to India, returning in April, 1923, and going again to India in October of that year. In 1925 she went to Paris to undertake the starting

or resurrection of a perfumery business, and in January, 1926, left Paris for Cannes, and took a pottery shop at Vence. There she became ill, and an operation for gall-stones was performed at the Anglo-American Clinic at Nice. The forceps was removed in September, 1928. It would have been interesting to know what was said by those who removed it, and whether attention was then pointedly drawn to the fact that it was a screw forceps, and not the sort of forceps which the French surgeons commonly used, although it was stated that thousands of such forceps were used in France during the war.

There is no kind of recollection (said the Lord Chief-Justice) so misleading as controversial recollection, and of all kinds of controversial recollections the least trustworthy are those which are fortified by a feeling of indignation. If any member of the jury has had an illness spread over a considerable period in some form or other, he will find that it is extraordinarily difficult, looking backwards, to be very precise about his symptoms at any particular period, especially if the trouble is of a kind which gives a diffused pain. We have been told that when the gall-bladder is affected a very common accompaniment is a flatulent dyspepsia, capable of causing great pain and discomfort, now here, and now there, a little difficult to locate. How difficult it is for a person who has suffered in that way, looking back over a longish period of years, to say with certainty that his symptoms at such and such a time were these, and not those.

His lordship reviewed the medical evidence, and stressed the long period, including accounts of illnesses in Paris and in India, as to which no medical evidence had been brought. There was, of course, the evidence of Dr. Stevens, relating to 1921–23. Dr. Stevens knew of the plaintiff's operation, and considered that she had ventral hernia, a common sequel to an abdominal operation in a stout subject; he never suggested that it was a case for an *x*-ray examination to see if there was some foreign body left in the abdomen. How came it that nobody who examined the patient in Bombay suggested an *x*-ray photograph? The plaintiff said that the lump was always there, about the size of a small coco-nut. Had any of these medical men suspected the presence of a foreign body would they not have taken steps to make sure? The plaintiff's statement was that the pain continued daily for eight years. Was that an exaggeration? Her expression that she felt as if she were eating rusty nails threw some light on the story, for who knew what it felt like to eat rusty nails? Was it not the sort of picture that would occur to a somewhat imaginative person, in all good faith, looking back after a period of time when she knew that a pair of forceps had actually been discovered? Finally came the operation by Dr. Prat in 1926. The jury might think that when all the surrounding circumstances were considered, together with the actual course of the operation of 1926, the forceps could not have been left in the body in 1920, and must have been the result of the operation five and a half years later at Nice. He then put to the jury the three questions already set out.

Verdict and Judgement.

The jury were absent only ten minutes. They answered in the negative the first question put—namely, "Is it established that the forceps was left in the plaintiff's body in the course of the operation performed by the defendant?"

The Lord Chief Justice thereupon entered judgement for the defendant, with costs.

Obituary.

SIR JOHN FAGAN, F.R.C.S.I.,

Consulting Surgeon, Belfast Royal Hospital and Belfast Hospital for Sick Children.

WE regret to report the death on March 17th of Sir John Fagan, Kt., F.R.C.S.I., at his residence, Craigeaverne, Portarlington, at the age of 86 years, after a long and distinguished career.

John Fagan, who was the eldest son of the late James Fagan of Lismacaffrey, Rathowen, co. Westmeath, was educated at St. Vincent's College, Castleknock, Dublin, and the Catholic University, Dublin; he afterwards studied in London, Paris, and Vienna. He obtained the diplomas L.R.C.S.I. in 1865, the L.R.C.P.I. and the L.M. in 1866, and the F.R.C.S.I. in 1874. He was surgeon to the Royal Hospital, Belfast, for twenty-five years, and was also surgeon to the Belfast Hospital for Sick Children—an institution which he was mainly instrumental in establishing. He acted as consulting surgeon to seven of the most important medical institutions in the North of Ireland, where he had an extensive consultation practice. In 1897 he was appointed Inspector of Reformatory and Industrial Schools. The methods of education and training then in vogue in these schools were completely changed by him, and the system now in operation was begun. The result of this method of training, which came before the public at the recent exhibitions by the Cork and Belfast schools, has called forth the highest encomiums from all interested in primary education. In 1906 Sir John Fagan was appointed medical member of the General Prison Board. He was a Justice of the Peace for co. Antrim and a deputy lieutenant for Queen's County. He received the honour of knighthood in 1910.

DR. WILLIAM HAMILTON ELLIOTT, who died on February 27th, at Castlerock, Londonderry, at the age of 82, received his medical education at the University of Dublin, where he graduated M.B. in 1870, and obtained the diplomas L.R.C.S.I. and L.M. two years later; he proceeded M.D. in 1875. For more than thirty years he was medical officer of the Londonderry (Waterside) and Glendermott districts, retiring in 1907. A colleague writes: One of the most courteous and gentlemanly of men, he was highly esteemed by everyone who came into contact with him, and his relations with his professional brethren were always of a most cordial and friendly nature. He resided latterly at Castlerock. His wife predeceased him several years ago.

DR. WILLIAM G. GORDON died on February 25th at Ballater, Aberdeenshire, where he had been in practice for the last six years. He graduated M.B., Ch.B. at Aberdeen University in 1905. At the beginning of the war, when he had been junior partner for a time in Malvern, Worcestershire, he was commissioned in the R.A.M.C., and served as captain in France and Flanders with that unit till 1917, when he was sent to England as the result of severe concussion and gas poisoning. From these injuries he never recovered. At the end of 1917 he resigned his position as surgeon in charge of Catterick Camp Hospital, and until he resumed practice in 1924 he was in continual bad health. Dr. Gordon, who was very popular in Ballater, is survived by a sister. He was a member of the British Medical Association.

DR. JOHN GREGORY WHITE, so long a leading practitioner in Bournemouth, died at Aspley Guise, Bedfordshire, on February 11th, at the advanced age of 92. He obtained the diploma M.R.C.S. in 1862, and graduated M.B.Ed. two years later. Dr. White settled at Bournemouth early in his career, and for a great many years conducted a very large practice when Bournemouth was developing rapidly and was mainly a select winter resort for invalids. His work was characterized by uniform kindliness and patience, combined with the practical skill in treatment which was the foundation of his reputation. He retired in 1907, and went to live at Aspley Guise, where he had inherited property, being succeeded in his practice by his son. Dr. Gregory White was a man of wide intellectual interests, and acquired a large circle of friends in Bedfordshire, among whom his death is greatly regretted. Twenty-three years having elapsed since Dr. White left Bournemouth, he was not widely known to the present generation; but there are still many among the senior members of the profession, and among the older residents of the locality, who cherish his memory with affection.—H. G. L.

The following well-known foreign medical men have recently died: Professor HERMANN PFEIFFER, professor of general and experimental pathology at Graz; Dr. HANS KNORR, extraordinary professor of orthopaedics and director of the Orthopaedic Institute at Heidelberg; Dr. PAUL SCHROETER, extraordinary professor of ophthalmology at Leipzig, aged 89; and Dr. PINÉGUINE, director of the Institute of Hygiene at Tashkent.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Army Estimates were discussed by the House of Commons in Committee on March 24th, and on the following day the Estimates for the three Defence Services passed through report. (A report of the debate on the Army Estimates will be published in our next issue.) Debates were arranged for subsequent days on wireless telephony, relations with Russia, and the cotton industry.

The Parliamentary Medical Committee met on March 25th. All the medical members present decided to back a one-clause bill safeguarding the superannuation payments of medical and other Poor Law officers transferred to local authorities of which these officers are members. Dr. Vernon Davies was expected to introduce the bill. At the same sitting the Parliamentary Medical Committee was addressed by Dr. Crowden on medical science and industry, with particular reference to industrial medicine in Germany and America.

In the House of Lords, on March 25th, Earl Russell, for the Government, introduced the Workmen's Compensation (Silicosis) Bill. The bill was read a first time.

Mental Treatment Bill.

COMMITTEE STAGE CONTINUED.

Consideration of the Mental Treatment Bill was resumed in a Standing Committee of the House of Commons on March 20th, when Clause 7 was discussed. This clause enjoins every local authority to appoint a visiting committee of not less than seven members of which at least two shall be women. Mr. GREENWOOD moved that the appointments should be annually. He said this would make statutory what was now the practice under Section 170 of the Lunacy Act. The committee agreed to the amendment. Further amendments, moved by the Minister and accepted by the committee, made the committee set up by the clause into a visiting committee for every institution maintained under the bill by a local authority, and provided that every subcommittee appointed by the visiting committee should include at least one woman.

Clause 7 was then added to the bill.

The committee agreed to Clause 8, which gives power to appoint one medical officer to supervise two or more mental hospitals. Miss LAWRENCE explained that Birmingham had used this power, and desired to have one supervising authority over all its asylums. The clause would allow other authorities to follow Birmingham's example. The bill did not contemplate a combination of local authorities for lunacy purposes or mental deficiency purposes. If the committee desired to modify the provisions for the uniting of local authorities under the Lunacy Act that must be done later in the bill. The present powers of the authorities to combine were untouched by the bill.

Clause 9, dealing with expenses of local authorities, was postponed, and Clause 10, "application to London," was added to the bill, with slight amendments, suggested by Dr. Fremantle.

Clause 11 provides for the reorganization of the Board of Control. Miss LAWRENCE moved to precede it with the words:

"The Board of Control shall consist of the chairman (who shall be a paid commissioner) and not more than four other commissioners, all of whom shall be paid commissioners."

Miss Lawrence said the Royal Commission had a Board of four members—a lay chairman, a legal commissioner, a medical commissioner, and a woman commissioner. The Royal Commission thought the present Board, whose duties carried them over the country so frequently, was not a proper body for dealing with administration. It recommended a very small Board, which would sit continuously in London, with visiting commissioners, called assistant commissioners. They considered the possibility of appointing two additional medical commissioners, but on further consideration rejected that from their recommendations. On these technical matters of organization the opinion of the Royal Commission, given after hearing many witnesses, should not be overruled unless very important considerations could be urged against it.

Dr. FREMANTLE moved that there should be six commissioners besides the chairman, instead of four, as proposed by the Government. He said that, along with Dr. Vernon Davies, he thought that it might be desirable to appoint two medical commissioners, one having experience of institutional administration and the other special scientific qualifications. His present amendment, however, suggested that the two additional commissioners should be a layman and a laywoman. That was not a professional recommendation, but made from the experience of the present Board of Control. The advice of the laymen and laywomen who had served the Board of Control had often been invaluable. A lay commissioner took the same view as the House of Commons, or as the public who wrote to newspapers. These two commissioners should be unpaid. Of the other four commissioners, at least two should be medical, and one should be a medical woman. A woman doctor was required to find out things concerning women patients. He did not believe that the chairman and four commissioners proposed by the Government could do any but exceptional formal and superficial visiting.

Mr. RHYS DAVIES asked for an assurance that the work of the Board of Control could be brought under review by the House of Commons.

Miss LAWRENCE said that as a machine the present Board of Control was bad. There were eleven commissioners. The chairman sat in Whitehall. With him sat one member regularly on a rota, week by week. The other ten were visiting in the provinces. That machine could not function as the guiding body of a great service should function. She did not blame the commissioners, but the machine. The Government desired a machine comparable to the existing machinery of the Ministry of Health—the chief officials engaged mainly in Whitehall, but visiting wherever the case seemed to them to require them, and, assisting them, expert visiting commissioners. Then this department of public health would be on lines resembling the other main departments of public health. To run about the country all day long was not the business of chief officers. There were not to be any amateurs. The commissioners were to be paid, full-time men and women—a chairman and four commissioners. Two were to have legal or medical experience. The woman might be either lay, legal, or medical; so might the fourth commissioner be. The Minister would be a layman, the secretary would be a layman, and the chairman would be a layman.

Captain GUNSTON asked why the Minister should not use the services of those who had given voluntary service on the present Board of Control. Were they not to use the services of Sir Leolin Forestier-Walker and of Miss Pinsent? Additional people of that sort would give the country confidence in the Board.

Mr. GREENWOOD said the Government proposal was a deliberate attempt to get away from the existing Board of Control. That was not a board of company directors, but an administrative machine carrying executive powers. The bill proposed to give an administrative machine, but Dr. Fremantle's amendments would extend amateur bureaucracy with no contractual obligations. It was the Minister's business, in the last resort, to represent the lay mind, and the addition of other commissioners would not get rid of his responsibility as the spokesman of public opinion. He did not see that the liberty of the subject was safeguarded by adding persons who happened to be unpaid. On that the Minister was responsible to Parliament.

Dr. FREMANTLE said local government was all the more efficient because it was unpaid. Unpaid commissioners would give the Board of Control prestige in the public mind, and would help in the work of administration. If Mr. Greenwood would not reconsider the proposal it would be raised in and out of Parliament during the report stage and in the House of Lords.

Mr. GREENWOOD retorted that in the past the existence of unpaid commissioners had not stopped public scandals.

By 19 to 8 the committee decided to retain four as the number of commissioners, in addition to the chairman. On the motion of Miss LAWRENCE the committee inserted words providing that the members of the Board of Control should be called "senior commissioners."

The next subsection of Clause 11 ran:

"Of the members of the Board of Control other than the chairman one at least shall be a legal commissioner, one at least shall be a medical commissioner, and one at least shall be a woman."

Dr. FREMANTLE moved as an amendment that "two at least shall be medical commissioners and one shall be a woman registered medical practitioner." He said this amendment carried out the Royal Commission's report. Very few men could really combine scientific work and administration. The proposal that one of the commissioners should be a woman practitioner was strongly put forward by the Medical Women's Federation and bodies speaking for women doctors, and by some mental welfare societies as well. He did not think it was put forward by the medical superintendents.

Miss LAWRENCE said the Royal Commission had not recommended the appointment of two doctors. It had said that was an alternative course which might be considered. The Government proposed one more commissioner than the Royal Commission recommended, and thought that enough. It left the fourth commissioner unearmarked.

Dr. Fremantle's amendment was negatived, and the committee adjourned.

On March 25th discussion of Clause 11 was continued.

Dr. FREMANTLE moved that all commissioners, and not merely the senior commissioners, on the Board of Control should hold their commissions direct from the King.

Miss LAWRENCE said the amendment struck at the whole plan for reorganization of the Board of Control. The commissioners

in a junior position were to be administrative officers under the Board and servants of the Board.

Dr. VERNON DAVIES said Dr. Fremantle and he were concerned solely from the point of view of heads of mental hospitals, some of them alienists whose names were known throughout the world. Visiting commissioners should be able to meet them on an equal status.

Miss LAWRENCE said it was illogical to say that visiting commissioners of the Board of Control should be of higher status than other inspectors of the Ministry of Health.

Dr. MORRIS-JONES supported the amendment, but Mr. Greenwood repeated the objections urged by Miss Lawrence, and the amendment was rejected by 17 votes to 7.

Miss LAWRENCE moved to omit the provision that a person may be appointed a legal junior commissioner or a medical senior commissioner if he either is qualified to be, or is already, a legal or medical commissioner, as the case may be, and to substitute the words: "No person shall be appointed a legal senior commissioner unless either (1) he is a practising barrister or solicitor of at least five years' standing; or (2) he is a commissioner, other than a senior commissioner, and was, at the date when he was appointed such a commissioner, a practising barrister or solicitor of at least five years' standing; and no person shall be appointed a medical senior commissioner unless he is a registered medical practitioner of at least five years' standing."

Mr. HOPKIN moved, as a further amendment, to substitute "seven" for five years as the qualification for the legal commissioner. He said this was the qualifying term for a borough stipendiary.

Miss LAWRENCE cited statutory precedents for the period of five years, which, she said, had the full approval of the legal profession for the old Lunacy Commissioners and commissioners under the Mental Deficiency Act.

Mr. Hopkin's amendment was defeated by 15 to 9.

Dr. MORRIS-JONES, in moving a similar amendment, said a young man of 26 in medicine was regarded as quite inexperienced, particularly in this branch. It was quite wrong that under the bill he could be appointed a member of the Board of Control.

Miss LAWRENCE said the amendment was frivolous and unreasonable. Five years was the old-established practice. The amendment was rejected.

Dr. VERNON DAVIES moved that the medical qualification should be five years' experience in the practice of psychological medicine. He said that at present, unfortunately, the medical curriculum had very little mental work in it.

Miss LAWRENCE feared the amendment would narrow the field. Some superintendents of hospitals with vast experience would be ruled out by this amendment. No one would dream of appointing a surgeon as a commissioner under the bill.

Dr. VERNON DAVIES offered to alter the wording of his amendment, and pointed out that special qualifications were required under the venereal diseases scheme and other Acts.

Dr. FREMANTLE remarked that there were instances where lunacy commissioners had been appointed who had not the desirable special experience.

Miss LAWRENCE promised that the point would be further considered. Dr. VERNON DAVIES then withdrew his amendment, and the principal amendment concerning qualifications which Miss Lawrence had moved was inserted in the bill.

Miss LAWRENCE then moved to insert: "After the commencement of this Act (1) no further unpaid commissioners shall be appointed; (2) the paid commissioners, other than senior commissioners, shall be appointed, subject to the approval of the Minister, by the Board of Control, and any commissioners so appointed shall be officers of the Board."

Dr. FREMANTLE challenged the proposal to forbid the appointment of unpaid commissioners. Why, he asked, forfeit the services of such persons? The decision which the committee had taken at the previous sitting against unpaid aid only applied to the senior commissioners on the Board of Control.

Miss LAWRENCE said it was a new idea that in any civil service department there should be gifted amateurs not subject to control. She would consult Mr. Greenwood before the report stage to see whether the services of present unpaid commissioners could be continued. She was not now speaking of the "Big Five," but of the officers of the Board.

Dr. FREMANTLE demanded the deletion of the embargo on the further appointment of unpaid commissioners. He said that Miss Lawrence was diminishing the status of the visiting commissioners by calling them officials. Not so could they keep the confidence of the public.

Dr. Fremantle's amendment was negatived. In response to Miss Picton-Turbervilie, Miss Lawrence promised that the bill would be amended on report to ensure that the visiting commissioners should include women.

Discussion followed on the salaries of the commissioners, which the bill enjoins the Minister of Health to fix, with the consent of the Treasury.

Dr. FREMANTLE remarked that judges and members of the Board of Control were the only persons whose salaries were fixed by statute. Miss LAWRENCE said the Minister was fully aware of the necessity of giving adequate and attractive salaries for this important work. The words of the clause were as wide as possible. They were a blank cheque to the Ministry of Health and the Treasury.

Clauses 11, 12, and 13 were then added to the bill.

On Clause 14 ("Transfer of certain powers from the Minister of Health to the Board of Control") Mr. WOMERSLEY moved that any dissatisfied local authority should have power to appeal to the Minister against any action of the Board of Control affecting it. Mr. Womersley said legal authorities doubted whether the Board was in fact responsible to the Minister.

Miss LAWRENCE suggested that the ordinary parliamentary responsibility of the Minister would suffice as a safeguard. The Minister appointed the chairman of the Board, and had power to investigate the files. Local authorities could bring difficulties to his notice. Difficulties could be raised on the Estimates for the Ministry of Health.

Dr. VERNON DAVIES pointed out that one of the transferred powers was to register or refuse to register hospitals which local authorities desired to set up.

Mr. GREENWOOD said the bill was endeavouring to short-circuit procedure and get rid of reduplicated effort. The amendment would complicate it again.

Mr. RHYS DAVIES said that the schedule of the bill increased the powers of the Board of Control, and he feared that the Board would not come under greater public review than in the past.

Mr. GREENWOOD denied that the bill conferred new powers on the Board. The powers which the clause proposed to transfer were minor matters, and the object was to ensure that two sets of people had not to handle the same plans, specifications, and contracts. The committee had sought to bring the Board of Control into closer relations with the Minister, but the amendment would set one against the other.

Mr. Womersley's amendment was rejected by 15 to 9. Clause 14 was added to the bill, and the committee adjourned till March 27th.

The General Medical Council and Indian Medical Degrees.

Mr. BENN, in reply to Mr. Freeman on March 20th, said he was aware that the General Medical Council had withheld recognition of Indian medical degrees. He was in communication with the Government of India on the subject, and could not at the moment make a statement, though he was anxious that a settlement should be reached. On March 24th Mr. BENN, in reply to Dr. Fremantle and Major Pole, said that he was aware that the decision of the General Medical Council would prevent holders of Indian medical degrees gained during the period of non-recognition from practising in this country. The Government of India informed him, on January 6th, that it did not expect to be able to introduce legislation for the establishment of a general medical council in India during the present session of the Indian Legislative Assembly. He had not heard from them since on that point.

Dr. FREMANTLE asked if Mr. Benn was taking steps to ask the Government of India if they would agree provisionally to make arrangements so that Indians who were qualifying for practice during the next six or twelve months might not be finally, and for the rest of their lives, debarred from practice. Mr. BENN replied that those were naturally matters on which he was consulting the Government of India.

Dr. VERNON DAVIES asked if Mr. Benn was aware that the cause of the dispute was the alleged statement that the training of Indian medical men was not considered sufficient. Mr. BENN said that it would not be suitable, in reply to a supplementary question, to deal with the whole question of medical training.

Medical Services in the Colonies.

The House of Commons, in committee, on February 24th, discussed a supplementary vote of £4,250 for salaries and expenses of the Colonial Office. Dr. DRUMMOND SHIELS made a statement on the work of the Development Fund Committee. The fund was set up to provide grants or advances to the Governments of the colonies, protectorates, and mandated territories to aid agriculture and industry. Dr. Shiels said that it would be agreed that the first essential to any development and substantial improvement in a colony, and to its capacity to afford employment to its own people as well as to people in this country was that the people in the colonies should be in a proper physical condition. The Colonial Development Advisory Committee had given considerable attention to proposals which had been put before it for improving the health and conditions of the people in the colonies, and had already reported favourably on more than twenty schemes for that purpose from many parts of the Empire. In Tanganyika Territory money was being provided in connexion with tuberculosis, which was fairly prevalent there. It was hoped that as a result of that work, increased knowledge would be gained

as to how to tackle this serious scourge in Africa, and especially in East Africa. Three venereal disease clinics were being established in Swaziland. In Somaliland steps were being taken, with assistance from the fund, to establish a supply of pure water. There were other water and drainage schemes in connexion with Freetown, Sierra Leone, which had been a very malarious port, and drainage works had been put in hand in St. Lucia and Dominica. A medical training school was being established in Tanganyika for a wide development of native medical assistance, which was a very much needed development in that country. The total cost of the various projects was in the neighbourhood of £170,000, of which £112,000 was being met either by direct grants or loans from the Development Fund. The House would feel that money spent in improving the public health of the colonies was money well spent.

Mr. AMERY said he was glad that those responsible for the conduct of the Colonial Development Fund had regarded the question of health as being within its scope. Nothing in the long run could lead to greater development of trade with the various colonies than anything which strengthened the health and efficiency of the population. Therefore he welcomed the expenditure on medical research and sanitary work, and hoped that it would continue. He wished to draw the attention of Dr. Shiels, who had referred to the sanitary conditions in the West Indies, to the defective state of many of the hospitals there. His attention was repeatedly drawn to them when he was in office, but so long as they were necessarily dependent on the revenue of small, impoverished colonies it was a difficult matter to remedy. The Development Fund could step in in a case of that sort and give assistance in a way in which it was very difficult to get from the Treasury, and when they would not be justified in getting it from local resources in view of the existing depression in the West Indies. If Nyasaland were to be opened up by the new connexion with the sea, it would be well worth while at the same time to relax a little the extreme rigour which limited its medical and sanitary services. Again, anything that could be done to conserve the health of the very fine race of natives in Swaziland merited attention.

Sir E. HILTON YOUNG congratulated the Advisory Committee on taking so wide a view of their functions, particularly as regarded the assistance they were giving to improve health conditions in the tropical colonies, and the far-sighted and enlightened manner in which they were prepared to give the assistance of the best expert advice. That was a clear example of what one might call the unearned increment to be gained from a very small investment of public money. There were some regions on the East Coast of Africa where whole populations were depressed well below the level of vigorous production by an endemic disease called ankylostomiasis. A small investment of money would result in raising the population to a higher level. One could not have a more conspicuous instance of how State expenditure could occasionally do good.

Mr. ORMSBY-GORE asked why the authorities did not employ on the Advisory Committee representatives of modern science. Dr. Shiels had told them that grants were being made for medical research and tuberculosis work in East Africa. Those were very admirable proposals, but he (Mr. Ormsby-Gore) questioned how far the committee, in its personnel as they had heard it, was fully qualified to decide between projects which were of major and of minor importance. He would have felt happier if it were clearly understood that when any project dealing, say, with medical development, was under consideration, either the medical adviser to the Colonial Office, the Secretary of the Medical Research Council, or the head of the London School of Tropical Medicine would be asked to join the Advisory Committee to give the other members full advice as to what was being done elsewhere and the best line to take. Had the committee established any principle or rule for the distribution of money? Did it, when it came to giving money to establish a particular institution, such as the new medical school at Dar-es-Salaam—if it were at Dar-es-Salaam—give, as a principle, what was called "fifty-fifty"? Did it give half the money to establish the new institution on condition that the territory locally found the other half; or was it clear to Colonial Governments that, if they put forward schemes for the consideration of the committee, the committee was prepared to give more than half the money required? He particularly rejoiced that the committee was going into the question of health services, and he hoped that the twenty schemes before it in that connexion would only be the forerunners of many more, because he knew of hundreds of cases in which some of the major requirements before economical development leading to employment here, and ultimate trade and expansion, were being held up by the scourge of tropical diseases, which was being fought gallantly by a small band of men and women. It needed the efforts of research workers in this country and out there, and further support, financial and otherwise, to help people who knew nothing of modern science out of the terrible death rate and sickness which obtained in those countries into a knowledge of how to protect themselves against infection, and how to deal with infection when they had got it.

Dr. SHIELS, replying to the debate, said that in regard to the building of the Zambesi bridge, which was one of the biggest schemes which had been signed, the wording of the contract to ensure the proper housing, medical and sanitary services, and the feeding and proper accommodation of all the workers engaged was at present the subject of negotiation and consideration. He assured Mr. Ormsby-Gore that the Advisory Committee had had the feeling that it was not expert in all services, especially in the health services. On the committee's initiative, a medical advisory committee was now being formed, apart altogether from the Research Committee, and he thought that probably in time it would become one with the Research Committee. That medical committee was being formed in response to the wish of the Advisory Committee to have a broad set of principles on which they could base their medical recommendations. The preparations had gone forward, and the medical committee was on the eve of being set up. With regard to other expert advice also, the Advisory Committee fully realized the importance of the matter.

The vote was agreed to.

Cancer as a Notifiable Disease.

A scheme for the nominal remuneration of medical practitioners for each case of cancer they reported to the local authority was explained to a Local Legislation Committee of the House of Commons, on March 25th, by Dr. R. F. M. PICKEN, medical officer of health for Cardiff. The scheme was included in a bill promoted by the Cardiff Corporation. The corporation asked that it should be lawful "to pay to any medical practitioner for each notification of a case of cancer within the city made, signed, and transmitted by him to the medical officer, a fee of two shillings and sixpence if the case occurs in the private practice of such medical practitioner; and of one shilling if the case occurs in his practice of medical officer of any public body or institution."

Dr. Picken said the corporation had taken a great interest in the incidence of cancer, and had for some time a voluntary system so that some idea might be obtained as to the housing conditions and the mode of life of the different cases. They had done this assuming they had the power under the Act of 1925. This clause was desired to remove any doubts on their rights in this matter.

Captain R. R. HENDERSON, a member of the committee: I suppose this is done mainly for the purpose of collecting statistics?

Dr. PICKEN. It is done mainly with the object of getting into touch with the patients and ascertaining the circumstances of their lives. I am a member of a Departmental Committee of the Ministry of Health, which feels this is one of the ways to discover something about cancer. Dr. Picken explained that no visits would be paid to a patient without the invitation of the practitioner in charge.

Captain HENDERSON: What about the breach of faith between the patient and the medical adviser? Suppose I had the misfortune to develop cancer, it would be most repugnant to myself and my family if, without my permission, I found my medical adviser had given information to the local authority. This is a fee or bribe to a medical practitioner to divulge illnesses from which his patients are suffering.

Dr. PICKEN said this power, if granted, laid no duty on the patient or practitioner. The practitioner was able to look after his own professional position. He did not think the large majority of patients would object to this intimation. Cardiff had been carrying on propaganda regarding the necessity of early treatment for cancer, and that would tend to make the scheme more popular. The clause was the product of a committee appointed by the corporation, consisting of experts and practitioners, entirely medical men. While some diseases had to be notified by law cancer had not. It was not proposed to make cancer compulsorily notifiable, but to give some encouragement to a voluntary system.

After a long consultation the committee decided not to pass the clause.

The Shops (Hours of Employment) Bill.

This bill, which proposes a maximum working week of forty-eight hours, exclusive of meal-times, for shop assistants, was read a second time in the House of Commons, on March 21st, without a division.

Dr. ETHEL BENTHAM said she had been for many years a panel practitioner, and could say the health of shop assistants compared badly with that of people in almost any other trade. They aged early and broke down early compared even with painters and bus conductors. There was a wide-spread idea in the trade that no woman who married after a long period as a shop assistant could have children, and there was some truth in the statement. Shop seats were a fraud and a delusion. There was bad ventilation in shops, and extremely bad lighting in many, particularly in the packing departments.

Mr. WOMERSLEY remarked that boys who were weaklings were put into shops.

Mr. SHORT, Under Secretary for Home Affairs, said the bill affected almost 2,000,000 workers. The Government proposed to set up a representative committee to inquire into the question.

Medical Officers in the Navy and Air Force.

In reply to questions by Dr. Vernon Davies, on March 20th, the following figures regarding medical officers in the Navy and Air Force were given by Mr. AMMON and Mr. MONTAGUE respectively.

Year	Medical Officers in the Royal Navy.			Medical Officers in the Royal Air Force.			
	Total number of medical officers.	Number entered.	Number retired, etc.	Year beginning April 1st	Strength at beginning of year.	Number who joined during the year.	Number who left during the year.
1920	454	24	29	1921	119	32	18
1921	429	12	37	1922	133	45	13
1922	415	34	38	1923	165	29	15
1923	392	14	37	1924	179	27	19
1924	393	33	32	1925	187	22	21
1925	390	29	32	1926	188	21	25
1926	390	30	30	1927	184	29	20
1927	381	37	46	1928	193	17	20
1928	390	45	36	1929	190	17 (*a*)	20 (*a*)
1929	372	19	37				

(*a*) Figures to date (March 19th, 1930).

The total numbers of medical officers in the Navy were those arrived at by the end of each year. Temporary surgeons entered during the war had not been included, and none were now serving.

Small-pox and Vaccination Commission.—Replying to Mr. Freeman, on March 19th, Mr. GREENWOOD said two of the British members of the Small-pox and Vaccination Commission of the League of Nations were officers of the Ministry of Health, and one was an official of the Medical Research Council. He was advised that this Commission, which was appointed in 1925, had had only a nominal existence since August, 1928. The Epidemiological Reports for October and November, 1929, had not been issued under its authority, but under that of the Health Section of the Secretariat of the League of Nations. Consideration of the subject-matter of these reports would seem to fall to the Health Committee of the League.

Medical Members of County and County Borough Councils.—Mr. GREENWOOD said, in reply to Dr. Fremantle on March 20th, that he could not introduce a short indemnifying bill to exempt present sitting medical members of county and county borough councils from their disabilities as from April 1st next. Dr. FREMANTLE pointed out that in rural parts of the country, particularly in Huntingdon, all practising medical practitioners were rendered ineligible for service as members of county councils by the provisions of the Local Government Act, 1929, and that such councils as desired to have medical members were unable to obtain them. Mr. GREENWOOD said only eleven days remained before the new Act came into operation, and local authorities had already made their arrangements. Dr. FREMANTLE replied that a good deal could be done in that time.

The Tuberculosis Service and Mental Hospitals.—Mr. GREENWOOD said, on March 20th, in reply to Dr. Vernon Davies, that any proposals by local authorities for an active liaison between the tuberculosis service and the mental hospitals would receive sympathetic attention.

Disease Attributed to Milk.—Replying to Mr. Wilfrid Whiteley, on March 20th, Mr. GREENWOOD said complete particulars of the number of epidemics of infectious disease attributed to milk were not available. Such information as was available was in the reports of the chief medical officer. In the returns of the Registrar-General no separate figures were given for disease attributed to milk. Replying to Dr. Vernon Davies, Mr. Greenwood stated that imported milk was subject to examination for tubercle under the Imported Milk Regulations, but it was not the practice to examine imported milk products for this purpose. He could not affirm that all these imports were from tuberculin-tested animals.

Inoculation against Diphtheria.—Mr. GREENWOOD told Mr. Freeman, on March 20th, that he was aware that Cardiff City Council proposed to perform the so-called Schick test and inoculate 10,000 healthy children under 10 years of age against diphtheria. Council proposed to perform the so-called Schick test and inoculate period to decide whether they will accept the offer of possible immunization from the disease. One month's notice was not practicable. Permission in writing was obtained before each child was treated.

Silicosis.—Mr. TURNER assured Mr. Hopkin, on March 20th, that he had no reason to think that silicosis was increasing in the anthracite district of South Wales. He hoped preventive measures, such as the compulsory use of water or of a mechanical dust trap while using percussive drills in sandstone or other highly siliceous rock, would check it.

Notes in Brief.

Sir C. Trevelyan told Sir John Ganzoni, on March 20th, that it had been a practice of many years' standing for the chief medical officer of the Board of Education to communicate directly with his colleagues in the school medical service in regard to questions which required their professional opinion.

A petition, signed by 102,816 persons, was presented in the House of Commons, on March 20th, which prayed that experiments upon living animals might be prevented by law.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

COUNCIL ELECTION.

MONDAY, March 17th, was the last day on which the names of candidates were to be received for the election of Members of the Council, which will take place on July 3rd. Three Members of Council retire in rotation, and the same three, applying for re-election, are the only candidates. They are Mr. Robert Pugh Rowlands, O.B.E. (Guy's), Member 1895, Fellow 1901; Sir Percy Sargent, C.M.G., D.S.O. (St. Thomas's), Member 1898, Fellow 1900; and Mr. Victor Bonney (Middlesex), Member 1896, Fellow 1899.

The constitution of the Council since July, 1929, has been as follows:

President.—Lord Moynihan, K.C.M.G., C.B., Council (1) 1912 (substitute) (2) 1919, President 1926.

Vice-Presidents.—Mr. C. H. Fagge, C. (1) 1921, (2) 1929; and Mr. T. Warren Low, C.B., C. (1) 1915 (substitute), (2) 1917, (3) 1926 (substitute).

Other Members of the Council.—Sir H. J. Waring, C. (1) 1915, (2) 1921, (3) 1929; Sir John Lynn-Thomas, C. (1) [illegible] Ernest W. Hey Groves, C. (1) 1911, (2) 1926; (2) 1927; Mr. F. J. Steward, C. (1) 1920, (2) 19[illegible] Mr. J. Herbert Fisher, C. 1923; Mr. W. (substitute), (2) 1929; Sir Percy Sargent, C. 1923 (substitute); Mr. G. E. Gask, C. 1923; Mr. W. McAdam Eccles, C. (1) 1914, (2) 1924; Mr. Willred Trotter, C. 1924; Sir Charles Gordon-Watson, C. 1924; Mr. A. H. Burgess, C. 1925; Mr. Victor Bonney, C. 1926 (substitute); Mr. G. Grey Turner, C. 1926; Mr. Hugh Lett, C. 1927 (substitute); Mr. Leonard Gamgee, C. 1[illegible] (substitute); Mr. R. G. Hogarth, C. 1928; Mr. R. E. Kelly, C. 1[illegible] Mr. Graham Simpson, C. 1929 (substitute).

The medical schools are represented as follows:

London:	
St. Bartholomew's	4
Guy's	3
London	1
St. Mary's	1
Middlesex	2
St. Thomas's	3
University College	1
Total London	15
Provinces:	
Birmingham	1
Bristol	1
Cardiff	1
Leeds	1
Liverpool	1
Manchester	1
Newcastle	1
Nottingham	1
Sheffield	1
Total Provinces	9
Total Council	24

UNIVERSITY OF OXFORD.

J. W. PUGH, B.M., University College, has been elected to a Fellowship on the Foundation of Dr. John Radcliffe.

UNIVERSITY OF LEEDS.

DR. F. S. FOWWEATHER has been appointed to the readership in clinical chemical pathology which the council has decided to institute.

Mr. B. Keaffreson has been appointed tutor in obstetrics and gynaecology, and Mr. J. J. Thomson as demonstrator in pathology and bacteriology.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

M.CH.ORTH.—M. G. Kini, D. W. L. Parker.

FINAL M.B., CH.B. (*1929 Regulations*).—*Part I:* A. M. Russell.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part A:* A. J. Galustian, J. M. Grieve, G. W. Phillips, R. Y. Stones, T. M. Tso. *Part B:* A. J. Galustian, J. M. Grieve, M. J. McHugh, G. W. Phillips, R. Y. Stones, T. M. Tso.

D.P.H.—*Part I:* J. H. St. B. Crosby, H. R. Dugdale, H. P. Fowler, J. D. A. Gray, E. Hughes, H. S. Lawrence, J. S. Mather, R. S. R. Menon, J. W. Pickup, W. J. Pierce, J. H. Pottinger, Nora M. Wilson.

DIPLOMA IN TROPICAL MEDICINE.—G. R. Baxter, C. J. Boyd, J. A. K. Brown, A. Cathcart, T. T. M. Chen, Ariel R. S. Deacon, J. H. Dobbie, F. D. Gillespie, S. C. Grant, R. Green, M. L. Gulatee, R. A. Hestlop, B. N. Khanna, D. K. L. Lindsay, J. E. D. Mendis, M. R. Modr, G. B. Mohile, S. Narain, C. J. Poh, L. Sumitra, T. Wilson.

DIPLOMA IN TROPICAL HYGIENE.—R. A. Anderson, C. G. Booker, W. A. Bullen, R. Krishna, C. N. Latham, J. E. McMahon, A. Reid.

UNIVERSITY OF MANCHESTER.

A CONSULTATIVE committee on cancer research, consisting of representatives of the University and of the Manchester Committee on Cancer, including the Christie Hospital and the Radium Institute, has been established. The research work will be conducted in the University laboratories, and will be directed and controlled by the consultative committee. Dr. C. C. Twort, who has been working under the direction of the Manchester Committee on Cancer, has been appointed as director of the department of cancer research.

Mr. John Morley, M.B., Ch.M.Manch., F.R.C.S., has been pointed lecturer in *systematic surgery*.

The following candidates have been approved at the examination licated:

D.P.H.—*Part II*: A. Brown, J. S. Sewell.

UNIVERSITY OF SHEFFIELD.

R. GRAHAM SIMPSON, F.R.C.S., senior surgeon to the Sheffield yal Hospital, has been appointed Professor of Surgery at the iversity of Sheffield, in succession to Professor A. M. Connell, o retires from office on March 31st.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

IE following degrees were conferred on March 19th:

.D.—W. A. Taylor.

.CH.—G. FitzGibbon.

.D., B.CH., B.A.O.—E. F. St. J. Lyburn, F. M. Lyons, P. O'Shea, R. T. O'Shea, F. O. Pilkington, A. Rose, G. F. West, J. Willoughby.

ICENCE IN MEDICINE, SURGERY, AND OBSTETRICS.—R. E. Hemphill.

The following candidates have been approved at the examinations licated:

INAL M.B., PART I.—*Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology*: *J. A. Wallace, L. FitzG. Burton, P. C. Cosgrove, J. B. Fleming, T. M. R. Ahern, N. H. Lesk, H. B. Wright, D. H. S. Boyd, W. A. Hill, H. J. Garland, J. G. Wilson, H. S. Mason, H. St. G. Smith.

PART II.—*Medicine*: W. J. Chapman, S. Levy, F. P. FitzGerald, P. L. O'Neill. *Surgery*: R. E. Hemphill, R. Bowesman, Annie E. Thompson. *Midwifery*: *S. H. Moore, *N. A. Kinnear, D. J. O'Ryan, T. A. Bouchier-Hayes, W. A. Robinson, C. H. Adderley, E. S. Duthie, C. H. Hutchinson, C. M. Elliott, C. Ryan, J. B. Scott, H. W. Dalton.

IPLOMA IN GYNAECOLOGY AND OBSTETRICS.—H. M. Fisher, E. T. Maskabadi, L. Yang, M. H. Rashwan.

* Passed on high marks.

UNIVERSITY OF BELFAST.

IE following candidates have been approved at the examination dicated:

M.B., B.CH., B.A.O.—J. H. Colhoun, Margaret M. Conway, C. E. Emerson, G. R. Garvin, S. B. Hughes, R. J. Huston, W. M'Bride, H. J. M'Elnane, G. F. Magurran, Nora Maybin, Phyllis E. Minford, H. F. Northey, T. H. W. Ritchie, C. V. Stevenson, J. B. Young, Mary C. Young.

SOCIETY OF APOTHECARIES OF LONDON.

IE following candidates have passed in the subjects indicated:

SURGERY.—J. Gordon, T. C. Keble, A. R. Madden, C. J. Nicol, S. E. Paterson, A. Scher, E. M. M. Shaw, C. Skinner, L. J. P. Soromenho.

MEDICINE.—T. Chandrasekharan, H. C. Halse, A. Hamid, E. G. Nair, R. Nandlal, M. S. Rappoport, T. Singh, G. K. Wilsker.

FORENSIC MEDICINE.—K. Graftdyk, H. C. Halse, A. Hamid, B. T. W. Harvey, L. Jacomb, M. S. Rappoport, T. Singh.

MIDWIFERY.—E. A. Freywirth, K. Graftdyk, J. M. L. Love, L. R. C. Rose, Grantley Smith, L. C. H. Sykes.

The diploma of the Society has been granted to Messrs. T. andrasekharan, J. Gordon, K. Graftdyk, H. C. Halse, A. Hamid, . T. W. Harvey, R. Nandlal, M. S. Rappoport, A. Scher, T. Singh, Skinner, L. J. P. Soromenho.

Medical News.

THE Durham County Council at its last meeting passed nanimously a resolution placing on record its sense of high ppreciation of the great public work rendered by Dr. Eustace ill during his service as county medical officer of health, nd expressing the hope that he will have many happy years i his retirement.

THE next evening reception at the Royal Society of Medicine ill be held at 1, Wimpole Street, W.1, on Monday, March 31st, t 8.30 o'clock, when members and their friends will be received i the library by the president and Lady Dawson of Penn. t 9 p.m. the film, "The Heir to Jenghiz Khan," will be hown. Admission will be by ticket only, for which application hould be addressed to the Secretary.

AT a meeting of the Royal Sanitary Institute to be held n the Council Chamber, Plymouth, on April 4th and 5th, iscussions will take place on the reconstruction and re-onditioning of working-class houses, on the purity of milk upply in the West of England, and on port sanitation; the hair will be taken at 6 p.m. On April 11th, at a meeting n the Town Hall, Chatham, at 4.30 p.m., Dr. W. A. Muir, M.O.H. Gillingham, will open a discussion on the adminis-rative control of infectious disease.

THE meeting of the Maternity and Child Welfare Group f the Society of Medical Officers of Health arranged for o-day (Friday, March 28th) has been postponed.

THE Fellowship of Medicine announces that from March 31st o April 5th a special post-graduate course in gastro-enterology ill be held at the Prince of Wales's Hospital, Tottenham, ccupying the whole of each day from 10.30 a.m. to 5.30 p.m. he mornings will be spent in clinical lectures and demon-trations, the afternoons in attending the general hospital ork and clinics, finishing with an hour's special lecture. o further special courses will begin until the end of April, but there are two weeks still remaining of the course in neurology at the West End Hospital for Nervous Diseases and of the course in medicine, surgery, and gynaecology at the Royal Waterloo Hospital, for which tickets at proportionate fees can be obtained. The subjects of the courses in April are: diseases of the throat, nose, and ear at the Central London Throat, Nose and Ear Hospital, from April 28th to May 24th; diseases of infants at the Infants Hospital from April 28th to May 10th; and psychological medicine at the Maudsley Hospital from April 28th to May 30th. Detailed syllabuses of all these courses may be obtained on application to the secretary of the Fellowship, 1, Wimpole Street, W.1.

AN appeal is being made on behalf of a memorial fund to be devoted to the development and extension of the children's department of Guy's Hospital, with which Sir Alfred Fripp was closely associated as a student, surgeon, and governor for over forty years. The fund will be used either for endowing cots, building a new ward, or any like purpose that the governors of Guy's Hospital and Sir Alfred's relatives may decide. Donations may be sent to the honorary secretary, the Sir Alfred Fripp Memorial Fund, 145, Cheapside, London, E.C.2.

AN international league for combating trachoma was founded at the thirteenth International Ophthalmological Congress. The president of the league, Professor Emile de Grósz, and the secretary, Dr. F. Wibaut, were entrusted with the formation of a committee composed of delegates from the various national ophthalmological societies. Up to the end of February forty-nine delegates had been nominated from twenty-six countries. The next meeting of the league will be held on July 26th in Geneva, and the programme will be issued at the close of May.

THE forty-fifth congress of the Balneologischen Gesellschaft will be held at Bad Elster, in Saxony, from April 9th to 13th. Particulars may be obtained from the general secretary, Dr. Max Hirsch, Berlin W.35, Steglitzer Strasse 66.

PROFESSOR LOEPER of Paris has been re-elected president of the Latin Medical Press, with Dr. Albert Delcourt of Brussels as vice-president, Dr. René Beckers as general secretary, and Dr. Jacques Rosenthal as treasurer.

THE twenty-first volume of the *Collected Researches* of the National Physical Laboratory, containing papers on electricity and wireless, has just been published by the Stationery Office (price 22s. 6d. net).

THE city of Vienna has decided to erect a monument to the late Professor Clemens Pirquet; and a street in Hamburg has recently been named after the late dermatologist, Professor Paul Unna.

Letters, Notes, and Answers.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocrity Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh)

QUERIES AND ANSWERS.

VISION OF MOTOR DRIVERS.

"SAFETY FIRST" would be glad to know if a man of 66 years of age with perception of light only in the right eye, but with very good vision in the left eye, will be debarred from driving a motor car by the Road Traffic Bill now before Parliament. He has driven a motor car for some years with this disability, and has never had an accident. Apart from the legal aspect, should he be advised to continue as before, or to give up driving a motor car?

TREATMENT OF ASTHMA.

DR. M. R. SONI (Manchester) writes: I would advise "M. E. P." (March 22nd, p. 575) to try hypnotism in the case of his patient who is suffering from bronchial asthma. If asthma cannot be relieved by adrenaline, and if an injection of morphine proves useless, then, in my experience, there is a strong hysterical element in the case, and hypnotism is likely to do good provided the patient can be hypnotized.

QUININE IN NORMAL LABOUR.

DR. H. J. HILDIGE (Pinner) writes: In answer to Dr. Ritchie's letter in the *Journal* of March 1st (p. 414) the following case came under my care this week. The confinement of a multipara, aged about 40, was due on March 4th. Since there was no sign of labour starting on March 20th it was decided to adopt the quinine routine. Accordingly at 11 a.m. half an ounce of castor oil was given, and an enema at 2 p.m. gave a good result. A hot bath immediately followed, a binder was applied, and 10-grain doses of quinine bi-hydrochloride were administered at 3 p.m., 6 p.m., and 9 p.m. Slight pains were felt at 10 p.m.; the membranes ruptured at 10.30 p.m., and the child was born at 2 a.m. in a condition of white asphyxia. After the mouth and air passages had been cleared out and the child had been immersed in a hot bath, it was soon in "full cry." I have used this treatment on two former occasions, I am glad to say without any untoward effects on the baby.

INCOME TAX.

Expense of Medical Reprints.

"X. X." who is a consulting surgeon, paid a sum of £25 out of his own pocket in connexion with the publishing and circulating among his medical acquaintances of reprints of a paper which he had read before a medical society. The inspector of taxes refused to admit the claim to deduct that expenditure for income tax purposes, but the Special Commissioners on appeal upheld the claim. The inspector has given notice that he is taking the case to the High Court. The publication of the paper would bring "X. X.'s" methods and name before practitioners in the neighbourhood, and, as a fact, his income did subsequently increase.

*** The legal position is not free from doubt. The essence of the objection taken (or which would be taken in the High Court) would be that the expenditure was of a "capital" nature and should therefore be disallowed for income tax purposes. (The objection that it represented advertisement, which a medical man is not allowed by the rules of his profession to do, seems to us too superficial to succeed, and apparently did not make much impression on the Special Commissioners who heard the appeal). Capital expenditure has often been a vexed question, but a fairly recent judgement by Lord Sands in the Court of Session—Commissioners of Inland Revenue *and the Granite City* Steamship Company, Ltd.—states the essential principle clearly. He said: "Broadly speaking, outlay is deemed to be capital when it is made for the initiation of a business, for extension of a business, or for a substantial replacement of equipment." Now "X. X." is *to some extent in a dilemma*: Either the paper in question was prepared and published with scientific rather than financial aims, or, if the latter object were in view, then to that extent the aim seems to have been "the extension of" his practice, and the expenditure falls within the "capital" prohibition. *On the other hand*, it is a commonplace that advertisement, in one form or another, plays an increasing part in modern life, and it is difficult to think that the principle invoked and so *stringently* applied in "X. X.'s" case is consistently so applied in dealing with ordinary business—in fact, the point made by the inspector, that advertisement must be ruled out in assessing medical profits in particular, lends colour to that suggestion. The precise stage which the appeal has reached is not yet clear. It is to be presumed that the decision as to whether *the case* will actually be taken to the Court of Session *does not rest with* the individual inspector, but with headquarters at Somerset *House or Edinburgh*. The inspector may possibly be referring merely to the preliminary steps necessary if the case is to be taken further. In those circumstances, and in view of the small amount of tax involved, it might be *advisable at this stage* for "X. X.," or his accountant, to take the matter up direct with headquarters with a view to ascertaining whether the case will really be taken to the Court, and, if so, whether, *as a new* principle—that is, that a medical man is in a special position in this matter—is alleged, the Revenue authorities will undertake to bear the legal costs. A favourable assurance *on the latter* point is unlikely, but some definite result might be arrived at as *the outcome* of taking the matter up with headquarters. *The* point presumably has no very wide application in the profession, and failing a settlement by consent, "X. X." might find it advisable to withdraw his claim rather *than face* the risk of substantial expense.

Replacement of Car.

"KLAXON" bought a car in 1926 for £245, and has received depreciation allowances aggregating to £81 for the period to March 31st, 1929. He *has now* replaced it by a new car costing £450, less £50 allowed in respect of the old car. What allowance should be claimed?

*** (1) Obsolescence allowance in respect of the unexhausted loss on the old car—that is, the amount of the written down value as at March 31st, 1929 (£245–£81=), £154, less £40 *received for it*, net allowance £114, to be treated as an expense *of the practice of the year* to March 31st, 1930. (2) Depreciation allowance for 1930-31, in respect of the new car, £450 at 15 per cent.=£67 10s.

Special Remuneration—Year for which Chargeable.

"E. W." sold his practice on June 30th, 1926, for cash. As a personal matter," having "nothing to do with the sale of the practice," he arranged to give an introduction for six months for which he was to receive £x "in April, 1927." The cheque was given to him on April 8th, 1927. For super-tax purposes that amount is being treated as income for the year ending April 5th, 1927. Is that correct?

*** Yes; the amount is chargeable for income tax purposes for 1926-27 because it was earned in that year and is a practice that year. Possibly "E. W." may have been somewhat misled by the rule applying to other kinds of income, such as dividends and interest, which are chargeable, not according to the period *of accrual*, but according to the date at which such income is receivable.

LETTERS, NOTES, ETC.

ILLUMINATION OF OPERATING THEATRES.

IN a recent issue of *E. T. Z.* (Berlin) H. Hartinges deals at length with the lighting of operating theatres. He points out that the requirements differ considerably from those of ordinary rooms, and that, as a result of experience, the method generally adopted nowadays is that of localized lighting of the operating field without any parasite reflections or shadows. Arc lamps were formerly used for the most part, but these are gradually being displaced by incandescent lamps. Hartinges describes one arrangement which consists of 100-watt lamps, with a reflector consisting of a glass parabolic back with a spherical nickel-plated metal extension. By means of five of such adjustable lamps a powerful light, without shadows, can be thrown on to the operating table. He next describes the Schubert arrangement by which the light of a projector with parabolic silvered glass mirrors is centred on the table by four mirrors. Some shadow difficulties have, however, to be contended with in this method. Descriptions are also given of the Burbier-Benard-Turrettini "Scialytique" and the German "Pantophos" lamp made by Zeiss of Jena. In the former an incandescent lamp of 150-c.p. capacity is located in the centre of a system of thirty-two mirrors, mounted on a cone. While the author considers that the arrangement is free from shadows, the fact that it is suspended by a chain may give rise to oscillations affecting the visibility; moreover, it has a somewhat high heating effect which inconveniences the surgeon and his assistants. In the Pantophos arrangement an opal lamp of 100 or 200 watts is used, this being centred in a deep silvered-glass reflector, practically ellipsoidal in shape. An auxiliary reflector, in the form of a spherical ring, is fixed in front of the lamp, which directs the rays of light back to the main reflector, the result being a powerful light without any shadow-casting.

HOLIDAY ADDRESSES.

THE *London Teachers Association Holiday Register of Addresses* 1930 contains a revised list of apartments, boarding houses, and hotels at home and abroad personally recommended by members of the association within the last four years or re-recommended by them within that period. Particulars are given of *number* of rooms available, distance from sea or station, principal rates, systems, and, in many cases, brief descriptions of *climate*, bathing, and other facilities. There are 234 pages altogether. The *Register* makes little provision, however, for the teacher who wishes to study the educational experiments in Central Europe. There are no references to Prague or to Budapest, and a single hotel address in Vienna seems insufficient when compared with 153 pages of English addresses. Copies may be obtained from the office of the association, 11, Pilgrim Street, E.C.4, at the price of 1s.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at *hospitals* will be found at pages 48, 49, 50, 51, 55, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 99.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

95. Herpes Zoster and Facial Paralysis.

VIGANONI (*Arch. Ital. di Otol., Rinol. e Laringol.*, January, 30, p. 14), who records an illustrative case, states that, cording to Ramsay Hunt, the action of the virus of herpes ster on the geniculate ganglion of the facial nerve may give e to a herpetic eruption on the external ear; the lesions ay spread to the facial and auditory nerves, causing two ner morbid conditions—namely, paralysis of the facial rve and disturbance of hearing. The triad so formed has en described under the name of "zoster syndrome of the niculate ganglion," or "complete herpes zoster oticus." is complete form may sometimes be replaced by incomete forms, or by associated forms in which neighbouring nglia are affected as well as the geniculate ganglion. The complete forms include herpes zoster of the external ear, rpes zoster with facial paralysis, herpes zoster with disrbance of hearing, and facial paralysis without herpes, but companied by pain only. Viganoni's patient was a woman, ed 42, in whom herpes zoster was associated with facial ralysis without any involvement of the auditory nerve. ie remarkable feature of the case was the appearance of cial paralysis a day before the herpes developed, whereas is more frequent for the paralysis to occur four or five days er the eruption of herpes. Another striking feature in ganoni's case was that after remaining unchanged for six nths in spite of electric treatment, rapid improvement ddenly began, and was followed by complete disappearance the paralysis in twenty-five days.

293. Epidemic Cerebro spinal Meningitis.

E. BONAR (*California and Western Medicine*, November, 29, p. 316) records his observations on 71 cases of epidemic rebro-spinal meningitis treated at the Salt Lake General ospital during 1927, 1928, and the first three months of 1929; per cent. of the cases were in the first decennium, 38 per nt. between 10 and 20, 11 per cent. between 20 and 30, and 5 over 30. Of the total of 44 deaths, 13 occurred within venty-four hours of admission. Omission of such deaths elded a corrected mortality of 23.5 per cent. The average ay of patients who recovered was eighteen days; 30 per nt. of the recovered patients showed one or more complicaons. Two were totally deaf on discharge, while four had paired hearing in one or both ears. Unilateral panphthalmia occurred in two patients, defective vision in one, id strabismus in one. Two patients had cervical adenitis, ne had nearly total paralysis of the right arm, and one itis and arthritis. The average dose of serum was 30 c.cm., hich was repeated according to the severity of the case at ght- to twelve-hour intervals. For the severe cases three jections were given during the first twenty-four hours, welve for the next two or possibly three days, and one daily ntil there was a definite change for the better. The average umber of punctures was eight. Intravenous administration f serum was used only for the severe septicaemic forms. isterna puncture was reserved for those with spinal block r patients desperately ill who showed signs of respiratory avolvement. No ventricular punctures were made.

297. The Heart and Circulation in Pulmonary Emphysema.

I. JAGIC (*Wien. klin. Woch.*, January 2nd, 1930, p. 18) directs ttention to the importance of hepatic congestion as one of he earliest symptoms of cardiac decompensation in pulonary emphysema. The liver is enlarged and tender on ressure and percussion. The patient complains of pain in he hepatic region, frequently attributed to the stomach. Acute hepatic congestion, due to sudden cardiac decompenation, commences frequently with intense pain, simulating holelithiasis, gastric or duodenal ulcer, or even appendicitis. Coincidently, cyanosis occurs, and, not infrequently, a subteric tint is seen in the skin. In the lungs, symptoms of ypostatic catarrh may be found in both lower lobes, and in very many cases of emphysema bronchial asthma (chronic spastic bronchitis) supervenes. Whatever the cause of decompensation, it is important that cardio-tonic treatment should be begun immediately. Caffeine is particularly useful; it acts as a cardiac tonic and relieves the bronchial spasm. Squill is also a most useful remedy. A combination of several drugs is often valuable. Jagic recommends a mixture containing caffeine-sodium benzoate, atropine sulphate, and tincture of lobelia. Digitalis should be reserved for the more severe forms of cardiac failure, in which hepatic congestion is often intense, and assists in the production of oedema and oliguria. In many cases the congestion disappears rapidly after injections of salyrgan, showing that the enlargement of the liver is not due only to circulatory congestion, but also to retention of water. Extensive oedema and oliguria are relieved by "fasting days," combined with "potato cures" and vegetable purées. In many cases of emphysema cardiac failure is progressive and calls for energetic cardio-tonic treatment. The ages of the majority of these patients range from 40 to 50; in addition to emphysema, they have severe cyanosis and other serious symptoms of cardiac failure. Pulmonary arterio-sclerosis is often present, and may render cardio-tonic treatment useless. Breathing exercises, inhalation therapy, hydrotherapy, and carbon dioxide inhalations in pneumatic chambers are useful in those cases in which severe symptoms of cardiac failure are absent.

293. Acute Diffuse Myelitis following Neo-arsphenamine Injections.

IN 1922 the Medical Research Council reported that the most important ill effects which might follow the administration of salvarsan and end fatally were encephalitis haemorrhagica, acute yellow atrophy of the liver, and exfoliative dermatitis and its complications. To these E. SCOTT and H. L. REINHART (*Journ. Lab. and Clin. Med.*, January, 1930, p. 405) add acute myelitis, and report a case which terminated fatally within two weeks of an intravenous injection of 0.9 gram of neoarsphenamine; a similar amount had been injected five days previously. Loss of sensation followed by flaccid paralysis developed from the legs upwards. The post-mortem examination revealed extensive degeneration of the blood vessels, diffuse degeneration of the white and grey substance of the cord from the lumbar to the cervical region, and complete destruction of the ganglion cells of the anterior horns, without any signs of exudation or glial proliferation. The only evidence of syphilis was provided by one positive reaction to a Wassermann test performed before treatment commenced, and a positive cerebro-spinal fluid reaction obtained after the acute cerebro-spinal symptoms had developed. The authors, therefore, eliminate syphilis as a cause, and classify the case as one of those rare fatalities which occasionally follow the injection of arsenobenzol preparations. In addition to the characteristic picture of arsenical poisoning in the cord, other evidence of this poisoning was shown by the destruction of the endothelium of the blood vessels, oedema of the brain and lungs, and a nephrosis. The authors consider that such cases should be classed with haemorrhagic encephalitis as one of the potential causes of death following the intravenous administration of arsphenamine.

Surgery.

299. Spondylitis Deformans.

I. W. NACHLAS (*Arch. of Surg.*, January, 1930, p. 159) defines spondylitis deformans as a chronic progressive stiffening of the spine grafted on a slowly increasing flexion deformity which leaves the back rigid in a stooping position; it frequently extends to involve the costo-vertebral joints, producing a rigid thoracic cage, and sometimes involving the hips and shoulder-joints. It usually occurs in young men in the post-adolescent period, and a case is described in which the patient was so bent that he faced the ground. The wall of his chest was motionless, leaving respiration entirely abdominal, and when lying on his back his fixed spine was still semicircular. Necropsies have shown the spinal rigidity to be due to an almost solid layer of bone surrounding the bodies of the vertebrae. Treatment should consist of the localization of any infectious process, with operative correction when possible. Out of 56 cases under review, foci of infection were found in 45, 26 occurring in the nose and throat, 15 in the mouth, and 23 in the genito-urinary regions; gastro-intestinal disturbances were noted in 4 cases. In each instance the necessary focal treatment was given, but it was found that in no case did lasting improvement follow the removal of foci of infection. Orthopaedic treatment, which consisted of an attempt to straighten the patient by making him lie on his back on a fracture bed or on a Goldthwaite frame, met with some success, one patient gaining 5 inches in height after resting for two hours a day on his back for five months. In some instances head and pelvic traction was necessary, opiates being given during the

stretching periods. When the maximum degree of straightening possible had been obtained a plaster-of-Paris support was made, and the patient was thus able to walk about and in some cases to return to work. As soon as the disease had run its course, which was usually when fusion had occurred, the support could be removed without fear of recurrent deformity. From the results obtained it was concluded that although gross obvious foci of infection should be removed for general hygienic purposes, yet radical operative procedure does not abolish the causative factor of the spondylitis, and corrective orthopaedic procedures offer the only hope of actual improvement.

300. Disinfection with Iodine and Tannin Spirit.

A. A. OZERELIEV (*Zentralbl. f. Chir.*, January 18th, 1930, p. 136) compared the merits of tincture of iodine and of 5 per cent. tannin spirit as disinfectants in 70 cases; in 35 the field of operation was treated with tincture of iodine, and in the other 35 with tannin spirit. In the former group 21, or 60 per cent., of the cultures taken from the field of operation (appendicitis or hernia) proved completely sterile, and in the latter 17, or 42.8 per cent., were sterile. At first glance the results appear to be in favour of tincture of iodine, but it must be taken into consideration that the 1 per cent. solution of sodium hyposulphite used for neutralization also had an inhibitory action on the growth of bacteria, so that the disinfectant action of the two fluids was about the same. Clinical observation, however, was decidedly in favour of tannin spirit. Of those cases in which tincture of iodine was used, 4 developed erythema of the skin, 1 a burn with vesicle formation, and 2 suppuration of the wound; whereas in the cases treated with tannin spirit uneventful healing of the wound ensued without the slightest sign of irritation. Spots left on the linen by tannin spirit can be removed with hot water and soap if so treated within forty-eight hours.

301. Treatment of Trigeminal Neuralgia.

M. DOGLIOTTI (*Med. Journ. and Record*, February 5th, 1930, p. 141) advocates the injection of alcohol into the Gasserian ganglion for the treatment of trigeminal neuralgia. He prefers this method to resection of the nerve root, since it is a much simpler procedure, the results are as good and it is followed less frequently by serious complications. After making the injection a light general anaesthetic is given. A needle of the type used for spinal anaesthesia is introduced about 2 to 2.5 cm. laterally and 1 cm. below the angle of the mouth. It is directed upwards and slightly backwards, so that it passes through the interpalatine fossa and ends at the lower surface of the lateral wing of the sphenoid. It is advisable at this stage, before attempting to enter the foramen ovale, to take an *x*-ray picture of the base of the skull, so as to ascertain the exact position of the needle. This is then passed through the foramen, care being taken not to press the needle farther than 1 to 1½ cm., when it will be in the middle of the Gasserian ganglion. If no blood or cerebro-spinal fluid escapes on removing the stylet, the needle is safely in the ganglion. The injection must be made very slowly (eight to ten minutes) to admit the gradual diffusion of the alcohol into the ganglion and to avoid a sudden invasion in other directions; only 1 to 2 c.cm. of alcohol should be injected. After the injection the needle is withdrawn for 1 cm. and washed with sterile water or saline in order to prevent traces of alcohol escaping and causing transitory motor disturbances of branches of the seventh nerve. The patient awakes with a nearly complete anaesthesia of the trigeminal nerve, and in two hours he is allowed to get up and go home. For five or six days it is necessary to protect the eye with a wet aseptic pack so as to avoid conjunctivitis and keratitis. If less than 2 c.cm. of alcohol is injected only two-thirds to three-fourths of the cells are destroyed; the remaining cells, after an initial paralysis, renew their function sufficiently to maintain the minimum degree of sensibility necessary for the protection of the eye and neurotropism. This method is particularly indicated in those patients who, owing to age or to the existence of arterio-sclerosis, nephritis, or diabetes, could not stand a severe operation.

302. Chronic Non-calculous Cholecystitis.

L. BACARANI (*Arch. di Med.*, December 14th, 1929, p. 1683) refers to all collected by Smithies, which showed that out of 1,000 cases operated upon 47 per cent. were not due to gall-stones. The symptoms of chronic cholecystitis are not unlike those of gall-stones; it is often associated with some septic focus in the tonsils, appendix, or teeth. The author suggests that the reason why such people develop symptoms of cholecystitis is because of some anatomical irregularity in the gall-bladder apparatus. Intervals of good health are quite common in these cases, and there may be typical attacks of pericholecystitis is present, wasting and a toxaemic appearance are common, suggesting malignant disease. Operation in this class of case gives excellent results. In cases of simple cholecystitis without adhesions the pain shifts with movement of the gall-bladder. Other cystitic symptoms may be due to stasis alone consequent on mechanical causes.

303. Paratyphoid C Cholecystitis.

C. ROMITI (*Trans. Roy. Soc. Trop. Med. and Hyg.*, November 1929, p. 25) records a case of cholecystitis in a male native of St. Lucia, aged 19, in which *B. paratyphosus* C was the causative agent of the disease. The case was remarkable for its acute course, the extreme mildness of the symptoms in spite of suppurative pericholecystitis and circumscribed peritonitis, spontaneous elimination of the necrotic gall-bladder into the cystic duct, the absence of gall-stones, and the very favourable post-operative course without formation of gall-stones. The patient also had a gluteal abscess following injections of quinine, in which *B. paratyphosus* C was found.

Therapeutics.

304. The Arsenobenzenes in Syphilis.

M. A. GALLIOT (*Paris Méd.*, January 25th, 1930, p. 83) contrasts the over-optimistic attitude, common at the commencement of the use of arsenobenzene preparations for syphilis, with the present-day tendency to pessimism. Too many authorities are inclined to regard syphilis as a chronic malady requiring long medication, whereas, in Galliot's opinion, it is an acute disease at the outset, and cure may be looked for if sufficient treatment is given at the right time. He adds that time is the only criterion of success, and it cannot be asserted, even yet, that absolute cure has been effected by arsenobenzene preparations, but a succession of cases treated before the war allows a sufficient lapse of time to give a probable indication of the results. Galliot has been able to collect nine such cases treated in the primary or secondary stage between 1911 and 1914 with the old salvarsan in two series of injections, and without treatment since. He finds that in all but two the Wassermann reaction has remained negative, and there have been no clinical signs of recurrence. Of the two resistant cases, in one it was noted that the Wassermann reaction did not become negative till after the second series of injections, a point which the author regards as indicative of either special virulence of the treponema or suitability of the patients' tissues for its multiplication. The amount of salvarsan given in the nine cases ranged from 9 to 5 grams. In two cases a lumbar puncture was performed, and the cerebro-spinal fluid was found to be negative, as well as the serum. Galliot considers that time and re-examination after a prolonged period without treatment are the only means by which the value of present-day preparations can be assessed; he is convinced that syphilis is curable if treated in the acute stage with adequate vigour and for a sufficiently long period.

305. The Therapeutics of Nitrogen Oxide Compounds of Morphine.

M. POLONOVSKI, P. NAYRAC, and J. TIPREZ (*Bull. de l'Acad. de Méd.*, February 4th, 1930, p. 174), who have prepared nitrogen oxide derivatives of morphine corresponding with those they had previously obtained in the case of scopine, amine, state that these compounds, which they term "pseudo-alkaloids," possess in a very general way a physiological action similar to that of the bases from which they are derived, but without having a very great toxicity. The morphine preparation ($C_{17}H_{19}O_4N$), which they term genomorphine, occurs in white crystals which are slightly soluble in water, the solution being neutral to litmus and alkaline to methyl orange; of its salts, the quininate, owing to its great solubility in water, is particularly indicated for therapeutic use. Genomorphine produces the well-known physiological effects of the opiate bases, allaying pain and giving rise to physical lassitude with a sense of well-being. Owing to its diminished toxicity it can be used in larger doses than morphine, 4 cg. of the former producing the sedative effect usually obtained by 1 cg. of the latter. Four cases are cited by the present authors to illustrate its beneficial effects; in two of these there were violent painful crises in jejunal peptic ulceration, chronic cholecystitis respectively, and in both relief was obtained in about half an hour. The other two were cases of post-operative pain. The effects of genomorphine are stated to be equally well marked in mental conditions, such as melancholia and hallucinatory delirium. In contrast with morphine this drug does not give rise to addiction, and the authors have found it useful in the treatment of morphine maniacs. Genomorphine is said to be indicated in those cases in which the toxicity of morphine and the fear of causing addiction have hitherto restricted its use.

306. Intramuscular Ether Injections in Whooping-cough.

LEVY and A. S. FINKELSTEIN (*Arch. of Ped.*, December, 3, p. 762) record their observations on a series of 104 cases whooping-cough treated by intragluteal injections of ether oil; 61 of the patients were males and 43 females, 15 were cured and 89 were white. The ages ranged from 2 months 10 years. To 94 patients was given a dose of 1 c.cm. of ether and 1 c.cm. of oil; 10 had 2 c.cm. of ether and 2 c.cm. oil. Of the 104 children, 75 were improved, 5 showed slight improvement, and 23 derived no benefit from the treatment. No patient, however, developed an abscess or necrosis in the area of injection. The skin was first cleansed with per cent. tincture of iodine; this was washed off with per cent. alcohol, and the injection was then given. The number of injections ranged from four to eleven, each buttock being used alternately.

307. Convalescent Serum Therapy.

H. KELLOGG (*Journ. Amer. Med. Assoc.*, December 21st, 1929, 1827) advocates the extended use of convalescent serum therapy in the pre-paralytic stage of poliomyelitis. Since the serum must reach the cerebro-spinal fluid for curative purposes, the intrathecal route would seem to be the most effective, though its injection into the blood, intramuscularly or intravenously, appears to be as effective except for some delay of the antibodies in reaching the spinal fluid. For prophylactic purposes during an epidemic, experiments on monkeys support the value of its use subcutaneously or intramuscularly, though the difficulty in obtaining serum may limit its application. In studying the value of convalescent serum the chief aim is to obtain a series of treated cases as a real control against a similar series of untreated cases as regards time, the stage of the epidemic, and the clinical type; full details should be recorded about the selection of controls. Experiments with normal serum would be worth while in view of the widespread immunity to the disease indicated by the low attack rate, the possibility that the so-called normal serum of young adults may often carry immune bodies in serviceable amounts, and the difficulty of obtaining an adequate supply of known convalescent serum.

Dermatology.

308. Tryparsamide in Pemphigus.

J. GRINDON (*Arch. Derm. and Syph.*, January, 1930, p. 25) reports several cases of acute pemphigus treated by tryparsamide. The Davis treatment of this condition by intravenous injections of iron cacodylate or sodium arsenate and subcutaneous injections of coagulen having failed in one case, Grindon was led to try tryparsamide, a pentavalent compound derived from atoxyl, on account of its low relative toxicity and its value in raising tissue resistance. In four cases of acute pemphigus success resulted from treatment with tryparsamide and coagulen as a modification of the Davis treatment. The treatment was tried also in two chronic cases; failure followed in one, but success in the other. In three of the four acute cases the improvement was rapid, but it was delayed in the fourth and the lesion did not completely disappear. Treatment consisted of intravenous injections of 2 grams of tryparsamide at weekly intervals, followed by two doses of 1 gram each. The author remarks that although the cases are too few to permit a final decision as regards the value of this modification of the Davis treatment, the results in the acute cases and in one of the chronic cases were certainly gratifying.

309. Treatment of Psoriasis with Ultra-violet Light.

I. JESSEN (*Ugeskrift for Laeger*, January 9th, 1930, p. 35) has treated ten cases of psoriasis with ultra-violet light from a quartz mercury lamp; several of them were very severe cases which had previously been treated unsuccessfully in various other ways. In every instance he completely cured, temporarily at any rate, his patients, some of whom had been treated with light from a carbon arc lamp with disappointing results. He found it necessary to regulate the dosage very carefully, determining in each case the exact dosage capable of provoking a slight erythema, which had completely disappeared the next day. Following this principle, he was able to increase the dosage gradually, and so avoid having to begin again with the small initial dose because an exposure, given while there was still an erythema from the previous exposure, had caused a too violent irritation of the skin. It proved useless to give such weak exposures that even transient erythema was not provoked. It was found necessary to remove the scales and scabs as completely as possible before each exposure. The author considers this treatment more effective than any other, whether the disease is recent or a relapse. In contradistinction to treatment with ointment, it has a remote action; in one case psoriasis of the scalp cleared up completely, although this part of the body had not been directly treated; it also has an after-effect. Unlike thorium-*x* treatment, it is not locally irritating, and, unlike *x*-ray treatment, it is quite harmless. Overdosage may provoke temporary irritation, but never an exacerbation of the disease. Ultra-violet light therapy is cleanly, and helps to mask the diseaas from the outset—a matter of great importance when the face is involved. Later also it has a cosmetic value, giving the patient a sunburnt and healthy appearance. In contradistinction to thorium-*x* treatment, it does not leave markings thereof, and the pigmentation it provokes is quite transitory. The administration is pleasant, and has a beneficial influence on the patient's general condition, nervous patients in particular enjoying the euphoria produced. If the patient possesses a quartz lamp and knows how to use it, this treatment is remarkably cheap, more so than treatment with ointment, which damages underwear and makes much washing necessary. The only objection to this treatment is the time it takes, but since it can always be ambulatory this does not matter so much.

310. Dermatitis caused by Picric Acid.

N. R. JACKSON (*Arch. Derm. and Syph.*, January, 1930, p. 40) reports five cases of dermatitis from picric acid, three following treatment with the solution alone, one the application of the solution and ointment, and one in a case of haemorrhoids in which the ointment alone was used, the applications resulting in an erythematous itching and burning dermatitis. The condition cleared up in a few days under treatment with wet dressings of normal aluminium acetate solution at first, and later with calamine lotion, menthol, and phenol. The author has failed to find references in the literature to picric acid as a cause of dermatitis, although the solution is employed extensively in the treatment of burns and in the preparation of the skin over the field of an operation, while butesin picrate ointment is used as an analgesic and soothing agent. He concludes that the dermatitis only develops in susceptible persons, and, considering how widely picric acid is used, it is probably of relatively rare occurrence.

Obstetrics and Gynaecology.

311. Clinical Features of Increased Folliculin Production.

ACCORDING to B. ZONDEK (*Zentralbl. f. Gynäk.*, January 4th, 1930, p. 1) excess of production of folliculin (the ovarian hormone found in cells and fluid of ripening follicles) can lead to amenorrhoea or to excessive bleeding, or to the one followed by the other. As an example of "polyhormonal amenorrhoea," the case is related of a married woman, aged 29, who, two and a half months after her last menstruation, was found to have bluish coloration of the vagina, a soft somewhat enlarged uterus, turgescent breasts with prominence of Montgomery's glands, and a cystic ovarian tumour. Extrauterine pregnancy was excluded by a negative Zondek-Aschheim reaction in the urine, which nevertheless contained an increased amount of folliculin. Surgical and other investigations showed: (1) that prior to operation the urine contained five times more folliculin than the blood; (2) that the cyst contained 60 c.cm. of clear fluid with 180 mouse-units of folliculin—from ten to twenty times the amount normally present in a follicle. The operation was performed eight and a half hours after commencement of a spontaneous uterine bleeding; curettings removed at the same time showed endometrial hyperplasia with an imperfectly developed pregravid phase. Eight days later the urine was free from folliculin, and normal menstrual cycles followed. From the biochemical tests of the urine a preoperative diagnosis was made of amenorrhoea due to overproduction of the ovarian hormone. The combination of amenorrhoea, hyperplastic and atypical endometrium, and utero-vaginal appearances simulating those of early pregnancy has previously been described in association with lutein cysts of the ovary. Zondek refers to excessive uterine bleeding in association with overproduction of folliculin as "polyhormonal bleeding," and thus agrees with the view expressed by Schröder and others concerning the etiology of "metropathia haemorrhagica." In such cases Zondek has found in the urine comparatively large amounts of folliculin, and in a persisting enlarged ovarian follicle three to five times the normal amount of folliculin. After such a follicle has been excised a normal menstrual cycle has been regained,

and in five instances Zondek has found the same to occur after deliberate rupture of the enlarged follicle during bimanual examination under general anaesthesia. According to Zondek the climacteric is characterized by three stages, usually successive: (1) increased folliculin production with soft enlarged uterus, and either bleeding or amenorrhoea; (2) diminished folliculin production with small hard uterus and pronounced vasomotor phenomena; and (3) the presence of increased amounts of prolan in the urine. In the third stage prolan A—that hormone from the anterior lobe of the hypophysis which induces ripening of the ovarian follicle—appears to excess in the urine, either because it cannot be utilized in the ovaries, or because these exercise an inhibiting action on the hypophysis.

312. Electro-coagulation in Chronic Cervicitis.

G. C. MOENCH and A. SCHULMAN (*Med. Journ. and Record*, February 5th, 1930, p. 131) maintain that attention to the underlying histopathology is essential in the treatment of chronic cervicitis, and that each diseased cervix presents an individual problem. A narrow external os with an inflammatory lesion behind it cannot be treated in the same manner as a hypertrophic, lacerated, and everted cervix. Owing to the disadvantages of the passive hyperaemia method of treatment the authors have reverted to cauterization, and prefer diathermy to the actual cautery. They use the Liebel Florscheim machine, a metal bivalve speculum being utilized as the inactive terminal and an aluminium needle or loop in a *vulcanite handle* as the active electrode, the point being passed up to the internal os. Cysts, if present, are punctured. For the erosion proper a spark-gap of 2 mm. is used and the whole area is coagulated. It is difficult to fix a *definite rule* for dosage and depth, which vary in different cases, but the authors have obtained the best results with a current of 500 to 600 *milliamperes*. Diathermy is practically painless, but in nervous women, or where a large area is to be *coagulated*, cocaine may be inserted into the vaginal canal. Of 200 cases treated by this method the results in only 100 are reported, these having been observed long enough to warrant conclusions being drawn. Of these, 83 patients have been cured, 13 have improved, and 4 have not improved. The following advantages are claimed for electro-coagulation over the cautery. It produces less heat in the vagina, and is more easily controlled; the risk of injury to the soft parts surrounding the vagina is less, and there is no odour of burning flesh as in cauterization; the resulting slough separates more easily, and the tendency to haemorrhage and stenosis is less. Electro-coagulation is also considered to be superior to surgery in that no inelastic scar is formed which might cause dystocia in future pregnancies.

313. Treatment of Chronic Adnexal Inflammation.

IN the treatment of chronic adnexal inflammation A. W. BAUER and H. LEHFELDT (*Zentralbl. f. Gynäk.*, December 14th, 1929, p. 3404) recommend rest in bed, vapour baths, the insertion of vaginal tampons of ichthyol or *iodine*, the application of leeches to the abdomen, and the oral administration of calomel. In twelve cases they have given injections of prolan (the preparation recommended by Zondek and Aschheim as containing in concentrated form the anterior hypophyseal hormone), for which the effect of inducing local hyperaemia in the pelvis has been claimed. In contrast with Zondek and Aschheim they found that prolan injections led to no more than a normal excess of the rectal or vaginal over the axillary temperature. Although the inhibition of prolan was followed by slight local and [illegible] reactions, the authors are not satisfied that [illegible] in the treatment of these cases.

Pathology of Precan[illegible] the B[illegible]

302. [illegible] should be [illegible] U BACCARANI [illegible] liest manifestations [illegible] to the figure [illegible] neoplasia [illegible] of 1,000 cases [illegible] within [illegible] with the view expressed [illegible] the etiology of "metro-gall-stones. The [illegible] the etiology Zondek has found in [illegible] cases Zondek has found [illegible] unlike those of gal[illegible] amounts of folliculin, and [illegible] septic focus in the [illegible] follicle three to five times [illegible] suggests that the [illegible] but follicle has [illegible] of cholecystitis is [illegible] After such a follicle has [illegible] in the gall-bladder [illegible] regained, [illegible] quite common in these [illegible] cycle has [illegible] of [illegible] attacks of colic. If [illegible] ria. In [illegible] astitis [illegible] 628 C

mazoplasia the breast is merely active when it should be at rest, and not in a precancerous state. Two diseases of the mammary gland that are definitely associated with the process of carcinoma are Schimmelbusch's disease and Paget's disease of the nipple. In the former the sequence of events is as follows. First, there is a desquamative cystiphorous epithelial hyperplasia; this is followed by a supervention of epithelial neoplasia that is definitely benign. Upon this second state supervenes an epithelial neoplasia with all morphological appearances of malignancy, and then comes the definite establishment of carcinoma. These processes are definitely attached to three decades of years—namely, the late twenties to the early fifties; the third stage occurs at the end of the second decade or at the beginning of the third. Paget's disease of the nipple affords distinct evidence of a preliminary epithelial neoplasia within either the ducts alone, or in terminal ducts and acini, *before* carcinoma appears. The morphological appearance of epithelial neoplasia may never be definite enough to enable a dogmatic statement to be made, and the determination of the danger must be based upon experience. An activity of growth in other tissues in contact with epithelial neoplasia is to be noted. For example, enormous localized hyperplasia of the elastica frequently occurs round only those terminal ducts and acini which contain the neoplasia from which the epithelial cells have invaded, and this would add a definite indication of the dangerous state of the enclosed epithelial neoplasia.

315. Toxin Formation by Bacterium enteritidis Gaertner.

A. MEYN (*Zentralbl. f. Bakt.*, January 7th, 1930, p. 163), working with seven strains of *Bact. enteritidis*, isolated from three months to five years previously, found that filtrates of two-day broth cultures were non-toxic to mice injected intraperitoneally in a dose of 0.5 c.cm., but that filtrates of fourteen-day and twenty-eight-day cultures proved fatal in one to two days. The lethal dose of the four-week filtrates varied with different strains, but was generally of the order of 0.05 to 0.25 c.cm. The toxicity of these filtrates was not diminished by steaming for half an hour. Using whole broth cultures, it was found that twenty ten minutes to destroy the bacteria, it was 0.05 to 0.25 c.cm. cultures were fatal in a dose of about 0.5 c.cm. The toxicity of the killed organisms did not appear to be greater in cultures incubated for fourteen days than it was in those incubated for only two days. Working with agar cultures that had been steamed for two, fourteen, minutes, it was found that the fatal dose of the 5 c.cm. and twenty-eight-day cultures was about 0.1 to 0.5 c.cm. agar cultures were washed off with saline, and the suspensions allowed to remain at room temperature, the lethal dose of filtrates after two days was about 0.5 c.cm., and after fourteen and twenty-eight days about 0.25 c.cm. From these results, two-day whole broth cultures, killed by heat, produced [illegible] while filtrates of the same cultures were non-toxic, the author concludes that the toxic substances must come from the bacterial bodies; with increasing length of incubation they are liberated by autolysis, and pass into the medium. Autolysis likewise is invoked to explain the rapid acquirement of toxicity of filtrates of saline suspensions of agar cultures. The author found that the toxicity of Gaertner cultures and filtrates was manifest only on parenteral injection. Given by a catheter directly into the stomach in a dose of 1 c.cm., none of the products proved toxic; even a whole agar slope, corresponding to between twenty and one hundred parenteral lethal doses, did not prove fatal. The author concludes that the toxins of Gaertner's bacillus are derived from disintegration of the bacterial bodies, that they are heat-stable, and that they are harmless when ingested by the mouth. This last conclusion is of importance in connexion with the etiology of food poisoning.

316. The Thyroid and Lipoid Content of the Blood.

S. SAKURAI (*Japanese Journ. Exper. Med.*, December 10th, 1929, p. 449) has found that if rabbits are bled to the extent of 5 c.cm. four times a day, at two-hourly intervals, there is a slight decrease in the amount of lecithin and total fatty acid content of the blood; if the same amount of blood is withdrawn once a day every second or third day for twenty-three days there is no change in the lecithin and fatty acid content of the blood. Parenteral injection of rabbits with 0.5 gram per kilo of body weight of ox thyroid emulsion causes a decrease of the amount of lecithin and fatty acid in the blood. Thyroidectomy in rabbits causes an increase of lecithin and to a less degree also of the total fatty acid content of the blood; the parenteral injection of ox thyroid emulsion into thyroidectomized rabbits temporarily inhibits the increase of total fatty acids, but has no apparent influence on the amount of lecithin. The author believes that functionally the thyroid gland is connected with the fat and lipoid metabolism of the body.

PHYSIOLOGICAL TREATMENT OF CONSTIPATION

COMPOSED OF

EXTRACT OF THE INTESTINAL GLANDS
which strengthens the glandular secretions of the organ.

BILIARY EXTRACT
which regulates the secretion of the bile.

AGAR-AGAR
which rehydrates the contents of the intestines.

LACTIC FERMENTS
anti-microbian and antipoisonous action.

TAKE X-RAYS TO YOUR PATIENT'S BEDSIDE . . .

YOUR patients will be the first to appreciate the convenience of X-rays in their own homes—no longer the irksome, or even dangerous necessity for moving to the nearest X-ray installation—the well-equipped doctor now brings the "Metalix-Portable" with him.

Made ready for use in a minute or two, the "Metalix-Portable" can be used wherever there is electric light. The owner is not called upon to master any technique or intricate mechanism, operation being by means of a simple time-switch. Danger from high tension and stray radiation is non-existent.

The quality of radiograms made with the "Metalix-Portable" is remarkable—ask the doctor who owns one or let us demonstrate in your own consulting room.

Simplicity, combined with accuracy and freedom from danger typify the "Metalix-Portable"—the outfit in use.

SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

A Valuable Surgical Co-operation

For the convenience of the Medical Profession we have arranged various visiting centres to which patients may be sent and fitted with

Individually made Surgical Appliances.

Practitioners will appreciate the advantages of having their patients fitted accurately to their prescription, rather than allowing them to run the risk of ill-fitting stock appliances.

We can also arrange to send expert male or female fitters to any part of the country. Fee quoted on enquiry.

An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:
Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

SPRING WEAR for DOCTORS

£1 PER MONTH

APPEARANCE is everything to the professional man, as nothing enhances status so much as good attire.

Most tailors study price, fit and finish, but few care what happens to your clothes after purchase, whereas Keith Bradbury, Ltd. provide a FREE VALET SERVICE for the care of their customers' clothes after purchase; garments are collected, brushed, repaired, sponged, pressed and returned like new.

Every consideration is given to the financial convenience of Doctors, who, more often than not, have to wait indefinitely for settlement of their own accounts. Arrangements are made whereby accounts can be disposed of half-yearly, quarterly, upon a £1 per month basis, or in any other way to suit individual requirements.

Distance need be no barrier to country practitioners, as the comprehensive Keith Bradbury self-measurement chart assures a perfect fit of all West End garments supplied by post—and to convince you that our confidence in this through-the-post service is not misplaced, we undertake to give you complete satisfaction or re-make the garments ordered.

An illustrated catalogue, patterns or full particulars of our special financial facilities will be gladly sent upon receipt of a postcard or telephone message, or perhaps you prefer to call and see us.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her; that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.*

INFLUENZAL "COLDS"

Alkaline therapy in some form has given the best results in all the recent epidemics of influenza and colds. The particular form of alkaline therapy represented by the administration of SALVITAE has always, when given a fair trial, proved to be the most dependable resource of all.

Samples and Literature on request to Sole Agents: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

A formula that demonstrates its scientific value.

Salvitae

Two sizes, 4/6 and 7/-

Manufactured by American Apothecaries Co., New York.

This preparation is now obtainable in 5-oz. bottles.

MIST. HEPATICA CONC. (Hewlett's).

Composition.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz.; 10-oz.; 22-oz.; 40-oz; and 90-oz. Bottles. Price in England, 12/6 per pound.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

C. J. HEWLETT & SON, Ltd., 35 to 42, CHARLOTTE STREET, LONDON, E.C.2.

A Remarkable advance in the presentation of H_2O_2

Also in exactly similar form and price—

SOLID IODINE

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement: also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-vol. strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 95, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

DIABETES

Brusson Bread has the lowest starch content of any starch-reduced gluten bread.

Its scientifically graded content of starch, protein, and fat enables the physician to prescribe the correct quantity for each patient. Liberal samples of Brusson bread on request, with copy of "The Amplified Diet in Diabetes," often very useful for handing to patients.

Apply to Superintendent.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

Viosterol "A. & H."

Irradiated Ergosterol *(Vitamin D)* in Oil

Biologically Standardised

Viosterol "A. & H." is standardised to contain 10,000 units of Vitamin D in each c.c., i.e., it possesses 100 times the Vitamin D activity of good Cod-Liver Oil.

Viosterol "A. & H." is the specific treatment for rickets, tetany and other disturbances of the calcium-phosphorus metabolism.

Special advantages of Viosterol are the small dosage required, its prompt effect, palatability and absence of digestive disturbances.

Viosterol "A. & H." is issued in special rod-stoppered bottles containing 5 c.c. and 50 c.c.

Special literature on request.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.
Tel.: 64117. *For terms etc., apply to the Medical Superintendent*

BELVOIR NURSING HOME,

Shanghai Municipal Council.

PUBLIC HEALTH DEPARTMENT.

ASSISTANT PATHOLOGIST.

An Assistant Pathologist is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than 30 years of age, and must hold qualifications in Medicine and Surgery of University standard: a D.P.H. and D.T.M. & H., though not essential, are desirable. Salary, Taels 650 per mensem, or Taels 700 per mensem if holding a D.P.H., under three years' agreement.

The agreement is renewable, in the event of satisfactory services, at a triennial increase of Taels 100 per mensem up to Taels 1,000 or Taels 1,050 per mensem if holding a D.P.H.

The Chief Pathologist, provided he holds the D.P.H., is eligible for the higher appointments of Deputy Commissioner and Commissioner of Public Health, the present maximum pay for which is Taels 1,350 and Taels 2,000 per mensem respectively.

First-class passage is given with half pay during voyage.

Eight months' leave is given on full pay, with first-class passage, after every period of five years' service in Shanghai.

Free medical attendance is provided, and there is participation in the benefits of a Superannuation Fund.

A Tael at the present rate of exchange equals about 1/11. Exchange is, however, subject to fluctuation.

Particulars of the appointment, and full details as to the benefits enjoyed by Municipal employees under their Terms of Service, may be obtained from Council's Agents.

Applications, in candidates' own handwriting, with full information as to their qualifications and experience, etc., accompanied by at least three recent testimonials, and endorsed "Assistant Pathologist" on the cover, should be forwarded to JOHN POOK & Co., Agent for the Municipal Council of Shanghai, 68, Fenchurch Street, London, E.C.3.

March, 1930.

Derbyshire County Council.

BRETBY HALL ORTHOPÆDIC HOSPITAL, near BURTON-ON-TRENT. (147 Beds.)

ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Assistant Medical Officer at the above Institution, at a salary, at the rate of £150 per annum, with board, residence, and laundry. The appointment will be for a period of six months in the first instance, and for a further period of six months at the option of the Council. The officer appointed will work under the direction of the Medical Superintendent. Preference will be given to candidates who have held resident hospital appointments and who are competent Anæsthetists. Orthopædic experience is not essential, but will be considered an additional qualification.

Applications, stating age, qualifications, and experience, together with copies of not more than three recent testimonials, should be addressed to the undersigned not later than April 7th.

New County Offices, St. Mary's Gate, Derby. W. M. ASH, County Medical Officer.

The Education Committee of the above Council require a School *Dentist to commence duties* at an early date. Salary £500 per annum. Candidates must be able to drive a motor van (equipped as a dental clinic). Further particulars can be obtained on application to the undersigned. Applications, giving details of qualifications, experience, etc., together with copies of not more than three recent testimonials, must be sent so as to reach the undersigned by first post on April 12th.

Education Offices, March. E. J. P. OSBORNE, Director of Education.

Manchester Ear Hospital,

Grosvenor Square, All Saints'.

NON-RESIDENT HOUSE SURGEON required. Salary at the rate of £150 per annum, with partial board. Appointment for six months. Applications, with copies of four recent testimonials, to be forwarded not later than April 12th to Mr. REGINALD S. MILFORD (Hon. Sec., Manchester Ear Hospital), c/o Mr. W. J. ELLAM, 33, Brazennose Street, Manchester.

County Borough of Southampton.

RESIDENT MEDICAL SUPERINTENDENT SOUTHAMPTON BOROUGH HOSPITAL.

The Corporation invite applications from qualified Medical Practitioners for the post of Resident Superintendent Medical Officer of their General Hospital.

Salary £600 per annum, rising by annual increments of £50 to a maximum of £700 per annum, with board-residence.

The gentleman appointed will be required during the pleasure of the Council, and his appointment will be subject to determination by two months' notice on either side. He will be required to carry out all duties in connection with a General Hospital, the treatment of patients, and generally to take charge of and supervise the Institution under the direction of the Medical Officer of Health.

The Local Government and Other Officers' Superannuation Act, 1922, will be applicable to the appointment, and contributions to the Superannuation Fund will be deducted from the salary. The selected candidate will be required to pass a satisfactory medical examination.

Form of application may be obtained from the Medical Officer of Health, Municipal Offices, Southampton.

Applications on the prescribed form, endorsed "Resident Medical Superintendent," stating age, qualifications, experience, etc., together with copies of not more than three recent testimonials, must be delivered at the Town Clerk's Office, Municipal Offices, Southampton, not later than before April 12th.

R. RONALD H. MORRIS,
March 24th, 1930. Town Clerk.

County Borough of Barnsley.

The Council of the County Borough of Barnsley invite applications for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer at a commencing salary of £500 per annum.

Candidates must be registered Medical Practitioners of at least three years' standing, and should have had experience in the work of a school medical inspection and routine work in child welfare. The possession of the D.P.H. and experience in ante-natal work, in the treatment of errors of refraction and in orthopædics will be considered additional qualifications.

The candidate appointed must devote his whole time to the duties of the office, and will not be allowed to engage in private or consulting practice, and will work under the supervision of the Medical Officer of Health who is also School Medical Officer.

Applications upon the prescribed form, which may be obtained from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), must be delivered to me on or before April 8th, endorsed "Medical Officer of Health."

The appointment will be determinable by three months' notice on either side.

A. D. MASON,
Town Clerk's Office, Town Clerk.
Barnsley.
March 17th, 1930.

Wanted at once, HOUSE SURGEON. Salary £150 per annum, with board, residence, and laundry.

Applications, stating essential particulars, with copies of testimonials, to be sent to the General Superintendent.

ROYAL AIR FORCE MEDICAL SERVICE.

VACANCIES EXIST FOR MEDICAL OFFICERS IN THE ROYAL AIR FORCE.

CONDITIONS OF APPOINTMENT.

Candidates will be selected after interview by a selection board without competitive examination. They must be of pure European descent. They must be British subjects, the sons of British subjects, and registered under the Medical Act.

Selected candidates will be appointed to Short Service Commissions for 3 years extendable to 5, and those under 28 years of age at the time of entry will be eligible for subsequent selection to Permanent Commissions, should they be desirous of remaining in the Service.

Resident Hospital appointments held since qualifying will, under certain conditions, qualify candidates for antedate of Commission; the age on entry to qualify for a Permanent Commission, if necessary, being increased by a period equal to the "antedate."

Excellent opportunities exist for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, Ophthalmology, and other special branches, adequate provision being made for permanent officers to attend Post-Graduate Courses of Study.

OUTFIT ALLOWANCE.

An officer who has not previously held a Commission in H.M. Forces will receive an outfit allowance of £70 on joining.

PAY, ALLOWANCES, PROMOTION, ETC.

The following table shows the Current Rates of Pay per annum for the various ranks:—

In addition to pay, Officers receive quarters, rations, and attendance, or are given cash Allowances in lieu as shown in the table.

Married Officers who have attained the age of 30 years receive either Married Quarters or Allowances at the Married Rates.

Service.	Rank.	Pay.	Allowances (Home rates).	
			Married.	Single.
On Entry	Flying Officer	£411	—	£127
After 2 years on promotion to	Flight Lieutenant ,,	£447	£229	£127
Rising by increments after 2 and 4 years to	,, ,, ... ,,	£574	£229	£127
After 10 years' total service on promotion to	Squadron Leader ,,	£784	£259	£161
Rising by increments after 2, 4, 6, 8 and 10 years to	,, ,, ... ,,	£876	£259	£161
By selection to	Wing Commander ,,	£911	£259	£161
Rising by increments after 2 and 4 years to	,, ,, ... ,,	£1,055	£259	£161
By selection to	Group Captain ,,	£1,201	£313	£251
By selection to	Air Commodore ,,	£1,372	£365	£365
By selection to	Air Vice-Marshal ,,	£1,735	£450	£450

Rates of Allowances abroad are fixed in relation to costs in the particular country.

The rates of pay of the R.A.F. Medical Branch are fixed on an inclusive basis, and the fact that specialist pay and charge pay are not payable as separate emoluments was taken into account when the rates were fixed.

GRATUITIES.

Short Service Officers who complete their full period of service on the Active List may be granted gratuity as follows on transfer to the Reserve:—

After 3 completed years £250
After 5 completed years £700

Permanent Officers who are allowed to retire voluntarily before qualifying for retired pay may be granted gratuity as follows:—

After 10 but less than 15 years' commissioned service £1,500
After 15 or more than 15 years' commissioned service £2,500

RETIRED PAY.

The current rates of service retired pay range from £470 a year, normally earned after 25 years' service, to £949 10s., the maximum for which an Air Force Marshal is eligible (at current rates).

Rates of retired pay are subject to alteration upwards or downwards within certain limits according to fluctuations in the cost of living.

Full particulars as to the conditions of service are contained in Air Ministry Pamphlet 25, a copy of which, together with form of application, can be obtained on application to THE SECRETARY, Air Ministry (D.M.S.), Adastral House, Kingsway, London, W.C.2.

Connaught Hospital
(100 Beds)
FOR WALTHAMSTOW, WANSTEAD, AND LEYTON, Orford Road, E.17.

Applications are invited for the undermentioned posts:

"The effect on the bowels has always been most marked"

The effect of a deficiency of Vitamin B upon the human system is not always observed, because it shows only as General Debility, Digestive Derangement, etc., for which other causes may have been assigned.

But when the deficiency is remedied by the addition of BEMAX the definite improvements recorded leave no doubt as to the cause of the indisposition.

The restoration of digestive health, the improvement in physical and nervous tone, are seen within a few days.

BEMAX is a natural tonic vitamin food prepared from the living embryo of selected cereals. It contains a higher proportion of natural Vitamin B than any other known substance, together with Vitamin A and E and valuable mineral salts.

Laboratory reports on BEMAX and a sample tin for personal trial will be sent to any medical man on receipt of his professional card.

C.O. 72.—I have prescribed it many times and the effect on the bowels has been the most marked feature.
—, M.B.

C.O. 86.—In a few days the child seemed full of energy.
—, L.R.C.P.

C.O. 132.—Marked improvement in health in about a fortnight. Constipation benefited.
—, M.D.

D. 5.—Immediately invigorates. It is very sustaining. I am sure it did me good.
—, L.R.C.P., L.R.C.S.

BEMAX

The Most Concentrated Extract of Natural Vitamin B.

THE BEMAX LABORATORIES, 38, DANEMERE STREET, LONDON, S.W.15.

PERCAINE

Trade Mark Registered.

The New Local Anæsthetic for Regional, Infiltration, Surface and Spinal Anæsthesia.

Vide *British Medical Journal*, March 15, 1930, pp. 488–9, and 495–6

TEXT-BOOK OF PATHOLOGY

By ROBERT MUIR, M.A., M.D., Sc.D., F.R.S., Professor of Pathology in the University of Glasgow. Second Edition, enlarged. viii + 872 pages, 591 Illustrations. 35s. net.

THE TREATMENT OF DISEASES OF THE SKIN

By KNOWSLEY SIBLEY, M.A., M.D., B.Ch.Camb., M.R.C.P., M.R.C.S., Physician to St. John's Hospital for Diseases of the Skin. Third Edition. viii + 248 pages, 24 plates. 12s. 6d. net.

LONDON: EDWARD ARNOLD & CO., 41 & 43, MADDOX STREET, W.1

"An important contribution to scientific literature."—British Medical Journal.

HEREDITY IN MAN

By R. RUGGLES GATES, Ph.D., F.L.S. Illustrated. 24s. net.

Hospital Gazette: "Professor Ruggles Gates has spared no pains to make his book comprehensible to those who are not familiar with the Science of Heredity."

Times Literary Supplement: "A useful contribution to a fascinating and important subject."

CONSTABLE & Co LTD
10 & 12 ORANGE ST LONDON W.C.2

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Senior Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

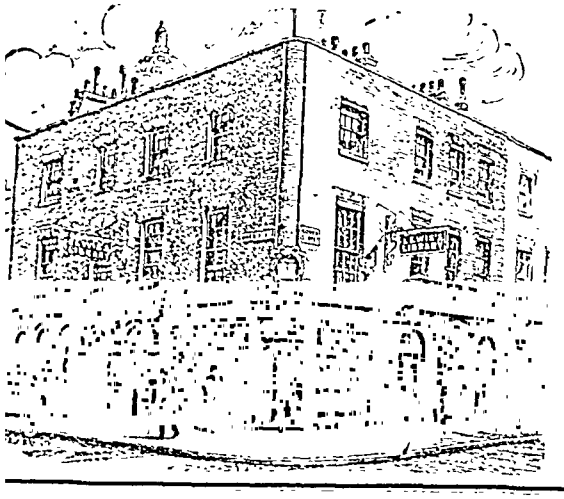
"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL ...

"A book ... to remain the standard work in Cardiology which we believe is destined ..."—AMERICAN MEDICINE.



"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its ... edition of his distinguished contribution to the increasingly important ... of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

A VERY WONDERFUL MOTORCAR—this HUMBER 16/50

WITH THE "SILENT THIRD" GEAR.

Press and public are unanimous in their opinion of the new Humber 16/50—a very wonderful motorcar summarises their verdict. Here.... in a car costing little over £400.... is luxury that is true luxury, beauty which has involved no sacrifice of comfort, performance that will please the most ardent sportsman—and above them all, quality! One of its many outstanding features is *the wonderful Silent Third (or "alternative top") gear for fast traffic work and hill-climbing*, with a remarkably simple gear change. Write now for the Humber Catalogue-de-luxe (MY/25) and our brochure "Press Impressions of the New Humbers" telling what the Press thinks of these cars.

A NATURAL, HARMLESS REMEDY FOR CONSTIPATION

PRUNOL Prune Jelly consists of: The best Prunes, stoned, and finely ground; Demerara Sugar; a small proportion of Green Ginger; about 7½% by weight of ground Senna leaves. Prunol Prune Jelly is Sir James Paget's well-known prescription for Constipation and Colitis. A dose of Prunol Prune Jelly has a continuing action lasting over several days, during which time the normal activity of the functions of the body is restored. The action of Prunol is always natural, easy and painless. It has no purging effect, like mineral salts or other well-known aperients. Prunol Prune Jelly clears the Colon of fæcal matter, and relieves Toxæmia immediately.

In jars 1/6 & 2/11.

The Treatment of Pulmonary Affections by Inhalation.

THE AËRISER

This instrument converts liquids into a voluminous but almost invisible vapour, or, in the words of the "LANCET," it "renders fluids like smoke," and thus enables medicated vapours to be inhaled continuously without injury to the delicate mucous lining of the air passages.

In all other sprays, atomisers, inhalers, etc., the spray is given off in palpable particles and cannot be used long without giving rise to discomfort. With the Aëriser, however, solutions, whether aqueous, oily, or balsamic, are given off in such a state of fine division that when the vapour is directed on to a sheet of glass or paper it remains unsoiled; consequently, when inhaled the medicament reaches the whole of the respiratory tract even to the innermost recesses of the lungs without causing the slightest irritation.

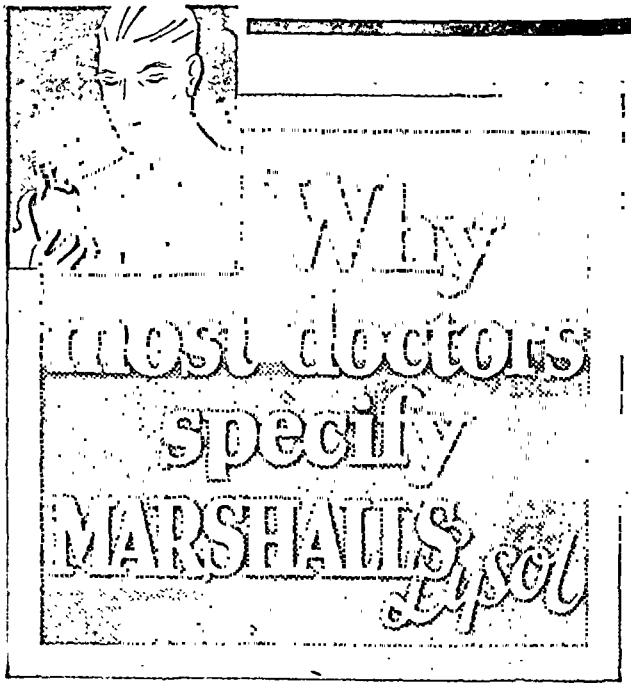
Irritable Bowel



Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

Nujol

MOST doctors say "Marshall's" automatically when they specify Lysol.

The reason is simple . . . the necessity vital.

There are many brands of Lysols and many liquids known as "Lysol Solution." Many of the former are impure, caustic, irritant. Two bottles of the same brand may vary enormously in quality. So-called "Lysol Solutions" are in most cases only 1/16th as strong as Marshall's Lysol.

Marshall's is the only Lysol made from the original formula and to the original specification. Every bottle of Marshall's Lysol is of a uniform high quality.

Marshall's Lysol really is an efficient and reliable antiseptic and is absolutely harmless when used as directed, but must never be used undiluted.

● ● *Sample sent upon request to members of the Medical and Nursing Professions.*

HOW GIBBS HELPS THE DOCTOR

Making a Nation Tooth-Conscious

Through Gibbs extensive advertising and their highly-organised educational work, the people of Great Britain are gradually being awakened to a realisation of the true value of their teeth.

This is one of the most valuable phases of Gibbs co-operation with Doctor and Dentist. On every hand the profession is bewailing the dreadful apathy of the public in dental matters. Gibbs endeavour to counteract this by vigorously setting out the tremendous advantages to be gained by developing and maintaining perfect teeth. Again and again the story is reiterated—health, beauty, success, happiness, depend upon perfect teeth.

By reason of this intensive, continuous effort, an ever-increasing body of the public is accepting the ideal of perfect teeth as a reasonable possibility.

When the history of dentistry in this age comes to be written, it will be recorded that the House of Gibbs, a frankly commercial organisation, had not a little to do with whatever progress is made by bringing about the practical application of the Doctors' and Dentists' ideals to the mass mind so that they were definitely realised in the individual.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Gibbs Dentifrice

BRITISH MADE

REGETHERM POULTICE

(Cataplasma Kaolini. B.P.C.)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

PRICE 2/- PER 1-lb. TIN

(NOTE THE WEIGHT).

Kolynos and the Saliva

The purpose of Kolynos Dental Cream is to clean the teeth and soft tissues of the oral cavity thoroughly, thus producing Sanitation of the Mouth. In accomplishing this Kolynos does not interfere with the normal reaction of the saliva.

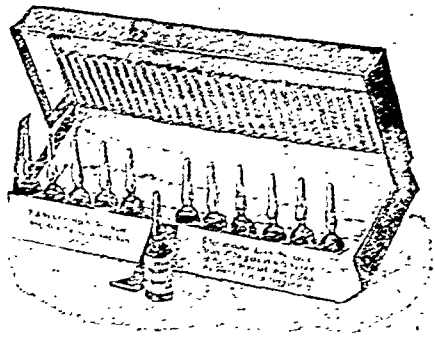
KOLYNOS DENTURE POWDER

An entirely new preparation for effectively cleaning artificial teeth. Can be used on the most delicate dental plate with complete safety and satisfaction.

Antiseptic. *Convenient in use.*

In the case of hand-reared infants the early use of fresh cow's milk modified by

Mellin's Food



will minimise risks and simplify the question of feeding.

Samples and directions for feeding average infants under normal conditions, as well as suggestions for the use of Mellin's Food in cases of diarrhœa, constipation, and malnutrition, are freely supplied to members of the Medical Profession.

The pamphlet "Modified Milk in Infant Feeding" will be forwarded with samples, post free, upon application to:—

MELLIN'S FOOD Ltd., LONDON, S.E.15

PITUITARY
(Posterior Lobe)
EXTRACT
B. D. H.

In the practice of endocrinology standardisation is of fundamental importance. Experience in the use of pituitary extracts proves that evaluation of the chief constituents is essential not only for success but also for safety.

Pituitary Extract B.D.H. is made to conform with the standard of activity laid down by the Therapeutic Substances Act; further, every batch of the extract is doubly tested and standardised in the B.D.H. physiological laboratories before issue to the medical profession—for its effect in the contraction of uterine muscle and for its pressor action.

Physicians, therefore, can always rely upon Pituitary Extract B.D.H. for uniform potency.

Pit. Ext. 73.

Toxæmias of Pregnancy

Biochemistry and Endocrinology prove beyond dispute that pregnant women are weakened in their defences against general disease and septic invasions.

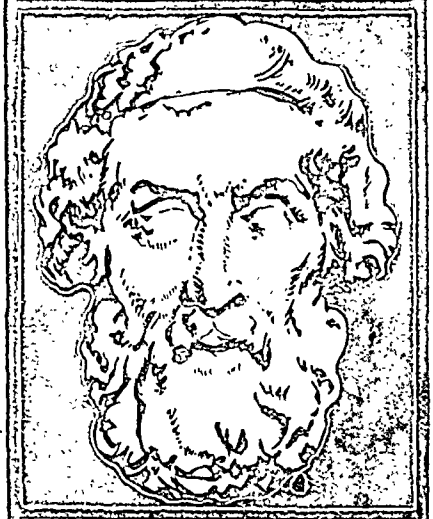
A lowered resistance, often accentuated by the modified shock of parturition, makes PUERPERAL SEPSIS only too simple a matter in many cases, in spite of faultless obstetric technique.

The toxæmias of pregnancy have been investigated and illuminated extensively in the past ten years by the patient research of many brilliant observers, who are all emphatic in representing the importance of intestinal toxæmia in the puerperal picture. Their conclusions point to the necessity of providing

A Safe Intestinal Bactericide

to promote the well-being of mother and child by limitation of putrefactive changes in the bowel during the later months of gestation, and until the post-puerperal period is passed.

Such a product is now available in the form of Dimol, the effect of which can be readily estimated by the gradual disappearance from the urine of the toxins—tyramine, indican, skatol, etc.



The Obstetrician who wishes to push his investigations into the fascinating subject of the influence of intestinal toxæmia upon intra-uterine life is now furnished with a powerful weapon of research.

The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

BUST OF HOMER

Intestinal Atony

For establishing a natural daily evacuation of the bowels "Cristolax" offers a desirable form of treatment in every respect. It is not habit-forming and obviates the need of purgatives, which often produce harmful results.

Under the use of "Cristolax" tone is given to the digestive process, inspissation of the fæces prevented and a healthy condition of the bowel maintained. Further, no leakage of oil occurs from the rectum, as usually happens when liquid or semi-liquid forms of paraffin are used.

Briefly described, "Cristolax" is a digestant, lubricant, and bowel eliminant. It is in the form of fine granular crystals, presenting an attractive appearance. The taste is so very palatable that the product has been described as being "as nice as sugar-candy."

MONSOL
in
MIDWIFERY

The antiseptic employed in midwifery must be both germicidally powerful and at the same time safe and free from danger.

Monsol is the ideal preparation in such cases because:—

(1) *It is selective in its action on streptococcal bacteria, being 10 times as powerful as lysol in this respect.*

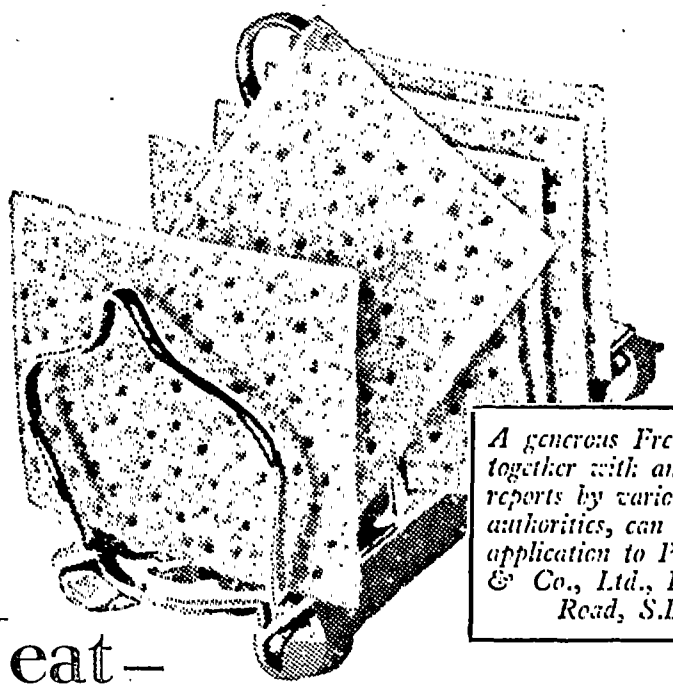
(2) *It has a perfectly non-irritant action on the tissues and mucous membranes at therapeutic concentrations.*

(3) *It keeps the hands and skin soft and does not roughen them.*

(4) *Is is a standard product and never varies in composition.*

Authorities competent to judge have expressed the considered opinion that the use of Monsol in midwifery reduces the incidence of puerperal sepsis by fully 90%.

Other authorities have also stated that certain lysol and cresylic acid preparations are not efficient germicides against streptococci without being used at concentrations which involve grave risk of injuring the tissues.



Monsol is so bland in action that it can safely be used at strengths far greater than germicidally necessary without any risk of causing irritation.

MONSOL PREPARATIONS INCLUDE:
MONSOL LIQUID, OINTMENT, INTERNAL CAPSULES, PASTILLES, DENTAL CREAM, TOILET SOAP, ETC.

Manufacturers:

Vita-Weat—
the perfect "staff of life"

Analysis and tests of Vita-Weat, the British whole-wheat crispbread, show that it possesses in a marked degree the six essential constituents—carbohydrates, fat, proteins, mineral salts, water, *and the essential vitamins.*

100% Whole Wheat.

Being made from the whole wheat berry, from which nothing has been removed in manufacture Vita-Weat yields the highest natural percentage of cereal proteins, and by the process of manufacture the starch present is rendered easily available for the solvent action of the amylolytic ferments of the human digestive juices.

Further, Vita-Weat is specially valuable as a natural stimulant to peristaltic action of the intestines, and when forming a suitable proportion of the daily diet effectively counteracts constipation.

Vitamins A, D and B.

The dry condition of Vita-Weat is of distinct advantage in cases of flatulence in which moist foods are largely contra-indicated, and the crisp character of the sections also helps to reduce the intake of soft foods, giving the teeth and masticating muscles something to do and ensuring complete and thorough salivation of the food bolus.

Vita-Weat crispbread presents the whole wheat berry in a concentrated, attractive and digestible form with the Vitamins A, D & B in an active condition, and it forms a valuable addition to rational diet, presenting a dainty and advantageous alternative to soft wholemeal or white bread.

Alternative Methods in the

TREATMENT OF BOILS CARBUNCLES & FURUNCULOSIS

Antivirus

The latest method, which has proved so useful with patients who object to injections, consists of local treatment with Staphylococcus Antivirus. Reports from hospitals and Skin Specialists state that this Antivirus is as efficient or more efficient than subcutaneous inoculations with Vaccine.

Detoxicated Vaccine

Practitioners who prefer the more orthodox forms of treatment are recommended to use Detoxicated Staphylococcal Vaccine; its special feature is the production of great immunity with little or no reaction. This is achieved by removing all the toxic elements of the germ during the preparation of the Vaccine. Doses up to 50,000 millions are given without malaise.

Ordinary Vaccine

To meet the requirements of those who consider that a slight reaction has definite therapeutic value Ordinary Staphylococcal Vaccine is available. It has proved generally successful and is very inexpensive.

STOMACH TISSUE
in
PERNICIOUS ANÆMIA

Recent publications in English and American literature indicate that hog's stomach is highly effective in the treatment of Pernicious Anæmia. This was especially noted in cases which did not respond satisfactorily to liver extract and in the treatment of achlorhydria, glossitis and paraesthesia.

In this connexion we have introduced

GASTREX

a carefully prepared, desiccated and defatted form of fresh hog's stomach tissue, presented as a finely powdered and pleasantly flavoured product. Supplies are now available for distribution to the Medical Profession, to whom full particulars will be sent on request.

Prepared at
Evans' Biological Institute,
Runcorn, Cheshire,

SOLUTION

FOR THE TREATMENT OF

ECZEMA & URTICARIA

Dr. Thos. M. Paul, in "The Urologic and Cutaneous Review," Vol. XXXIII, No. 11, 1929, reports that:—

"Eczematous conditions and Urticaria will readily respond to subcutaneous injections of the above preparation."

We have a precis of the above article and will promptly despatch this to interested Physicians on receipt of their card.
